Physician Heads Child Care Committee—Announcement has been received of the recent appointment of Dr. Ellen C. Potter, Trenton, as director of medicine and chairman of the child care committee of the Office of Civilian Defense Director of the State of New Jersey. Others on the committee include Dr. Julius Levy, Newark, consultant to the bureau of maternal and child health, state department of health, and representatives from the state department of public instruction, the state department of labor and various agencies of social work concerned with child welfare.

Sale of Vitamins Curbed—The New Jersey Board of Pharmacy announced on January 28 that vitamin preparations that are sold exclusively as foods or food accessories and the labels of which bear no directions for use in the prevention,

mitigation or cure of disease must be labeled "not for medical use" when sold in New Jersey. Otherwise the board will consider the vitamin products as coming within the classification of drugs and medicines within the meaning of the pharmacy act. It was announced in the *New York Times*. A properly balanced diet is the best source of necessary vitamins, it was stated, and it is up to physicians to decide if and when vitamins are needed for the treatment or prevention of disease, and in such cases the concentrated vitamins in the usual capsule form in proper dosage may be prescribed and, of course, in such cases they are drugs.

NEW YORK

Chemical Warfare—A postgraduate course on the medical aspects of chemical warfare will be conducted for the Tompkins County Medical Society at the county memorial hospital, Ithaca, February 16 under the auspices of the committee on public health and education of the state medical society and the health preparedness commission of the state war council. The speakers will be Neal E. Artz, Ph.D., Syracuse, and Dr. John J. Bourke, Albany.

New York City

The Harvey Lecture—Dr. William J. Robbins, director of the New York Botanical Gardens, will deliver the fifth Harvey Society Lecture of the current series at the New York Academy of Medicine, February 18. His subject will be "Some Internal Factors Limiting Growth."

The Brickner Lecture—Dr. Martin Silberberg, assistant in pathology, New York University College of Medicine, will deliver the eleventh Walter M. Brickner Lecture at the Hospital for Joint Diseases, February 26 on "The Influence of the Endocrine Glands on Growth and Aging of the Skeleton."

Rheumatism Organization Formed—The New York Rheumatism Association was formally organized January 22 to unite physicians in New York and environs who are interested in arthritis and rheumatic disorders to improve the treatment of patients with arthritis, particularly those attending the arthritis clinics in Greater New York and to stimulate research on these disorders. Officers are Drs. Russell L. Cecil, president; Martin H. Dawson, vice president, and Edward F. Hartung, secretary-treasurer.

NORTH CAROLINA

Physician Reported Missing in Action—Lieut. (j.g.) Walter Earl Brown, M.C.U.S., Navy, formerly of Rocky Mount, has been reported missing in action in the performance of his duty and in the service of his country, newspapers recently announced.

OHIO

Changes in Health Officers—Dr. James F. Wilson, Washington Court House, health commissioner of Fayette County and secretary for many years of the Fayette County Medical Society, has been appointed health commissioner of district number four of the Michigan Department of Health with headquarters in Rogers City, Mich.—Dr. Hazellett A. Moore, Oxford, chairman of the Butler County Board of Health since 1939, has been appointed health commissioner of the county. He succeeds Dr. Clifford J. Biddridge, who resigned.

TEXAS

State Health Officer Reelected—Dr. George W. Cox, Austin, was recently reelected state health officer for a two year term beginning January 1. He has held the position for six years.

Personal—Dr. Marie Elizabeth F. Gentry was recently named director of the maternal and child health division of the Austin City Health Department, succeeding Dr. William W. Kelton, Jr. who has entered the army air corps.—Dr. Patty Jane Byars, Fort Worth, was recently named medical adviser of the Texas League for Planned Parenthood. Dr. Byars recently returned to Texas after three years at the Massachusetts Memorial Hospital, Boston.

Pharmacologist Becomes Professor of Medicine—Dr. Raymond L. Gregory has relinquished his professorship of pharmacology at the University of Texas Medical Branch, Galveston, to accept an appointment as professor of medicine and director of the outpatient clinic and continuation courses at the school. Chas. D. Lerke, Ph.D., dean of the school and formerly professor of pharmacology at the University of California Medical School, San Francisco, will temporarily assist in teaching pharmacology at the medical school with Dr. Gregory and other members of the staff.

GENERAL

New Editorial Board for Endocrinology—A new editorial board has been announced for *Endocrinology*. Members are Dr John S L Browne, department of medicine McGill University Faculty of Medicine Montreal Canada Earl T Engle, Ph D, department of anatomy, Columbia University College of Physicians and Surgeons, New York, Carl G Hartman, Ph D, department of zoology, University of Illinois Urbana Ill, Edward C Kendall, Sc D, division of biochemistry, Mayo Clinic, Rochester Minn Fred C Koch Ph D, department of biochemistry, University of Chicago Dr Cyril N H Long, department of physical chemistry, Yale University School of Medicine, New Haven, Conn, and Dr Harry B van Dyke, Squibb Institute for Medical Research, New Brunswick, N J. The managing editor is Dr Edwin B Astwood of the departments of medicine and pharmacology, Harvard Medical School, Boston the associate managing editor is Edward W Dempsey, Ph D, of the department of anatomy of Harvard. A statement of the new policies for the journal appears in the February issue of *Endocrinology*.

Adjustments of Wages of Hospital Employees—By General Order No 26 adopted by the National War Labor Board, January 22 adjustments in the wages or salaries of employees engaged in rendering hospital services and employed by nonprofit organizations maintaining and operating hospitals will be deemed approved without submission to the board provided such adjustments do not raise the wages or salaries beyond the prevailing level of compensation for similar services in the area or community. Monthly reports of such adjustments must be submitted to the Division of Review and Analysis of the National War Labor Board, together with such information and data as the division or the board may from time to time require. Such adjustments as are made will be subject to the board's ultimate right of review on its own initiative, but any modification or reversal of the adjustments will not be retroactive. On the other hand, adjustments which will have the effect of raising the wages or salaries above the prevailing level of compensation for similar services in the area must be submitted for approval by the board in the usual manner.

Follow-Up on White House Conference on Children—A summary of the two and one-half year follow up program of the White House Conference on Children in a Democracy sponsored by the National Citizens Committee, has just been published. The program, which has been financed by short term grants, ended on January 1. The New York Office has been closed, but the National Citizens Committee will remain intact so that it can be called together when independent citizen action is called for. Miss Katharine F Lenroot Washington, D C, chief of the Children's Bureau, U S Department of Labor, and executive secretary of the White House Conference, has agreed to take over responsibility for correspondence and cooperation with state White House Conference committees and with national organizations in the follow-up program. Miss Lenroot has assigned the responsibility follow up within the bureau to Emma O Lundberg, who has been associated with previous White House Conferences and served as assistant secretary of the 1940 conference. All future correspondence concerning the follow-up program of the White House Conference should be sent directly to Miss Emma O Lundberg, Children's Bureau U S Department of Labor, Washington, D C. The National Citizens Committee was one of two appointed by the 1940 White House Conference on Children to implement its one hundred recommendations in the field of education child health and social welfare. The other, the Federal Interagency Committee, was formed to bring about a working relationship among all the federal offices in any way concerned with children. The report mentions that state follow-up committees were initiated in Arizona Arkansas, California, Colorado Connecticut, Delaware Florida, Indiana, Kansas, Louisiana Massachusetts Minnesota, Montana Nebraska, Nevada North Carolina Ohio Oklahoma Oregon South Carolina, Texas Utah Vermont, Virginia, Washington Wisconsin Wyoming and Puerto Rico and as a result of these activities improvement in considerations in child care was effected in nearly every state program. As a result of its 1941 state White House Conference the Nevada Committee was largely responsible for improvement in adoption laws and legal control for interpartum examinations for venereal disease. The Ninth Regional Conference sponsored by Florida's Committee resulted in the increase of state appropriations for the Aid to Dependent Children funds from \$140,000 to \$2,000,000. The report indicates that the work of the committee was instrumental in bringing about more concentrated programs

throughout the country. During its two and one-half year existence it has worked toward the objectives for which it was created: appropriation and dissemination of educational material working for the cooperation of national organizations in furthering the objectives of the 1940 White House Conference; cooperation with governmental agencies in matters relating to the follow-up program and assistance in the development of state territorial programs adapted to the needs and interests of the state.

Tropical Medicine Study Begins at Army Medical School—The Association of American Medical Colleges has made available a list of those taking the course of tropical medicine at the Army Medical School Washington D C under the sponsorship of the association with the financial aid of the John and Mary R Markle Foundation.

LONDON

(From Our Regular Correspondent)

Dec 26, 1942

Increase of Tuberculosis in Belgium

The Swedish Committee for the Relief of Belgian Children received during November a report that the food situation in Belgium is heading for a catastrophe. It is generally estimated that 2,725 calories is the minimum necessary for maintenance of life. When the committee began to work in the autumn of 1941 the number consumed in Belgium averaged 1,300. Since then the situation has persistently deteriorated, and according to official figures the number of calories dropped to 886 in July 1942 and rose temporarily to 920 in August.

The effect of this undernourishment is appalling. It has produced an alarming increase in tuberculosis, especially among young persons and children. It is evident that if improvement of diet does not take place tuberculosis will become rife in the whole population and weaken the race. For those who have small fixed incomes it has become almost impossible to buy the few commodities still for sale, because of the increase in price.

Scientific Journals for Enemy Prisoners of War

A request for scientific journals made in the *British Medical Journal*, the scientific journal *Nature* and the *Nation* in order that they may be supplied to enemy prisoners of war has met with the following response. Fifty-eight people have sent 2170 reprints and journals and 34 books on technical and scientific subjects for the use of scientists and physicians who are prisoners in British hands. The papers have been classified according to subjects. The special interests of the prisoners in the various camps are known, and parcels containing 956 papers and journals have been sent to 32 camps. So far only a small part of the demand has been met.

Those willing to contribute journals, reprints of books on scientific, technological or medical subjects are asked to send them to John R. Baker, Burnt Oak, Kislington, near Oxford, to write their name and address on the outside of the parcels with the letters "S P P" (scientific papers for prisoners) and to be patient in awaiting acknowledgment, as the classification and packing have to be done by Mr. Baker and his wife in the time they can spare from work and civil defense service. The S P P has the approval of all the authorities concerned with the welfare of enemy prisoners of war.

A Safety Hat for Women War Workers

There has been no compulsory style of head dress for women working at machines in war factories, so that many have allowed vanity to override safety, with the result that hundreds of accidents have occurred from hair being caught in the machines. Careful research has been devoted to the production of caps which would be safe, but women have refused to wear them because they were not sufficiently becoming, detrimental to the hair style or uncomfortable. The directorate of a group of thirty factories therefore approached the workers and asked them to put forward their own ideas on the subject. A competition was promoted of which the conditions were that the hat should be attractive and comfortable, contain the worker's hair with a high degree of safety, be hygienic and easily laundered, and have no loose ends. Several hundred designs were submitted. A panel of judges, consisting of a government inspector of factories and four women, selected twenty designs. They took into account the suitability of the design for manufacture in quantity as well as the amount of safety. The winning design came from a woman, to whom a prize of \$250 was

awarded. It is a neat fitting hat, which, viewed from the front has a trace of military smartness but for the rest is mainly of the fish net type, enclosing the hair, yet cool to wear.

The War Work of the Society of Friends

Though the Society of Friends cannot reconcile war with their religious beliefs, they have in this war, as in the previous great war, devoted energy and resources to the relief of the suffering produced and shared much of the danger of the combatants. In the Middle East they have a unit of more than 150 members, some of whom are working under the auspices of the British Red Cross, especially on mobile surgical units. They manned a hospital at Tobruk until that place fell. The report on the third year's work describes the establishment of mobile clinics in Syria to which Moslems, Christians and Druse resort, the distribution of medical supplies on the Burma Road, the salvage of \$600,000 worth of medical supplies from the Rangoon docks when the Japanese were closing in and their transport for 3,000 miles into the northern provinces of China, the provision of surgical aid for the rugged towns of Burma, sending surgical teams to help the Chinese on the Yunnan front, organization of first aid posts in view of possible air raids on Indian cities and sending forty men including two doctors for medical work in outlying regions of Ethiopia, where there are few facilities for combating the high incidence of sickness. A unit for work in the emergency medical service and other hospitals in England is also mentioned.

Sir Norman Walker

The death of Sir Norman Walker has removed a leading figure in the medical profession. Born in 1862, he graduated at the University of Edinburgh in 1884. After a few years in general practice he returned to Edinburgh in 1890 and spent the next few years in postgraduate study. He was attracted to dermatology and in 1892 was appointed assistant physician for diseases of the skin at the Edinburgh Royal Infirmary. He was also appointed lecturer on dermatology at the university. He visited the continent and became a disciple of P. G. Unna of Hamburg, whose pioneer work *The Histopathology of Diseases of the Skin* he translated from the German. Unna, with whom he was on intimate terms, expressed himself as fortunate in his translator. He also translated from the Norwegian Hansen and Looft's 'Leprosy in Its Clinical and Pathological Aspects'. In 1899 he published his most successful "Introduction to Dermatology," which went through ten editions. He had great aptitude for administration and in 1907 was elected representative for Scotland on the General Medical Council, of which he became president in 1931. On behalf of the council he paid two visits to India, where he inspected all the medical colleges and several of the numerous medical schools. From 1929 to 1931 he was president of the Royal College of Physicians of Edinburgh. He was also editor of the *Scottish Medical and Surgical Journal* and of the *Edinburgh Medical Journal*. He has left three sons, of whom, one, Dr. E. R. C. Walker, is a prisoner of war.

Marriages

WILLIAM WYATT HOBACK, Bethesda, Md., to Miss Sara Florence Crockett of Hillcrest, Va., December 21.

THOMAS FOSTER WHELDON, Richmond, Va., to Miss Gladys Pearl Jenkins of Frostburg, Md., December 26.

RAYMOND RIVKIN, Jamaica, N. Y., to Miss Helen Goldstein of Tampa, Fla., in Jacksonville, Fla., in October.

JOSEPH E. ACKER JR., Knoxville, Tenn., to Miss Elizabeth Chase Gutch of Palo Alto, Calif., November 19.

EDWIN BROOKS WERNICHER, Shreveport, La., to Miss Nellie Sue McNeil of Philadelphia, Miss., October 1.

Deaths

Harry Bond Wilmer ☉ Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1906 associate professor of allergy at the Medico Chirurgical College Graduate School of Medicine, University of Pennsylvania specialist certified by the American Board of Internal Medicine member of the American Association for the Study of Allergy and the American Clinical and Climatological Association, fellow of the American College of Physicians, served as a captain in the medical corps of the U S Army and was stationed at Base Hospital number 10 during World War I, director of medical services and physician in chief, department of allergy Abington (Pa.) Memorial Hospital associate physician and chief, department of allergy, Presbyterian Hospital, aged 58, died, January 16, of heart disease

Arthur Julius Skeel, Cleveland University of Wooster Medical Department Cleveland 1897, member of the Ohio State Medical Association formerly professor of anatomy and lecturer on obstetrics at the Cleveland College of Physicians and Surgeons, past president of the Ohio Obstetric Society, president of the Cleveland Academy of Medicine in 1925, served as president of the Hospital Obstetric Society of Ohio, fellow of the American College of Surgeons, a founder of the obstetric outpatient dispensary, consulting obstetrician and for twenty-eight years directing head of the department of obstetrics at St Luke's Hospital, where he died, December 7, of lobar pneumonia, coronary sclerosis and hypertensive cardiovascular disease, aged 68

George B Kunkel, Harrisburg Pa., University of Pennsylvania Department of Medicine, Philadelphia 1893 member of the Medical Society of the State of Pennsylvania fellow of the American College of Surgeons, served during World War I on the staffs of the State Hospital for Crippled Children, Elizabethtown, the Harrisburg, Harrisburg State, Harrisburg Polyclinic and the Keystone hospitals, served as president of the Pennsylvania Railroad Surgeons' Association and as surgeon for the Philadelphia and Reading Railroad, for many years a trustee of the Gettysburg (Pa.) College, aged 74 died, December 22, of pulmonary embolism

Fred L Adams, Wesley, Iowa State University of Iowa College of Medicine, Iowa City, 1898 formerly a druggist, aged 69 died, December 14, of cerebral hemorrhage and arteriosclerosis

Mary Alice Asserson, New York Cornell University Medical College, New York 1901 served as assistant university physician and on the staff for twenty-four years at Teachers College, Columbia University, for many years connected with the health department of New York, at one time secretary of the children's service of the New York Tuberculosis and Health Association, aged 71, died, January 10, of carcinoma of the liver

Charles E Bayan, Chester, Ark (licensed in Arkansas in 1903), member of the Arkansas Medical Society, aged 57, died, November 25, in the Veterans Administration Facility, Fayetteville, of carcinoma

Pern Jefferson Bidwell, Toledo, Ohio, Starling Medical College, Columbus, 1904 served during World War I on the staffs of the Lucas County and St Vincent's hospitals, aged 63, died, December 23, of coronary occlusion

George A Blaylock, Perryville Mo Barnes Medical College, St Louis, 1903 member of the Missouri State Medical Association, past president and secretary of the Perry County Medical Society, aged 63, died November 9 of carcinoma of the liver

Thomas Emory Camper, Corunna Mich Hahnemann Medical College and Hospital of Philadelphia, 1924 member of the Michigan State Medical Society and the American Public Health Association in 1936 established and directed the Iron County Health Department and in 1940 established and directed the Shawassee County Health Department aged 45 died, January 3 in the Memorial Hospital, Owosso of coronary occlusion

Ott Casey ☉ Clinton, Ind Medical College of Ohio Cincinnati, 1908, served as county coroner for two periods and as a captain in the medical corps of the U S Army during World War I, formerly health officer of Clinton aged 60, died December 29, in the Veterans Administration Facility, Danville, Ill, of coronary arteriosclerotic heart disease

Charles White Churchill, Thomson Ga University of Georgia Medical Department Augusta, 1909, member of the Medical Association of Georgia served as county physician and local surgeon for the Georgia Railroad for many years aged 63, died recently of heart disease

Charles David Collins, Milwaukee, Wisconsin College of Physicians and Surgeons Milwaukee 1902 served during World War I served on the board of appeals and in various other capacities in the Veterans Administration in Washington D C for many years, aged 64 died December 21, of cerebral hemorrhage

Raymond Lawrence J Cooley ☉ Buffalo University of Buffalo School of Medicine 1913 aged 50 on the staff of the Mercy Hospital, where he died, December 22 of heart disease

Edward Alfred Franklin, Los Angeles Columbia University College of Physicians and Surgeons, New York, 1905 aged 58, on the staff of the Hollywood Hospital, where he died, November 4 of coronary occlusion

Adolph Goldhammer, New York Columbia University College of Physicians and Surgeons New York 1896 aged 69 died December 27, of arteriosclerosis

John Nelson Goltra, Evanston Ill College of Physicians and Surgeons, New York 1887 member of the Illinois State Medical Society, veteran of the Spanish American War, formerly on the staff of the Sault Ste Marie (Mich) Hospital, author of "Health and Strength" aged 83 died January 15, of arteriosclerosis and myocarditis

Alva Silas Grimm ☉ St Marys W Va College of Physicians and Surgeons Baltimore, 1885 an Affiliate Fellow of the American Medical Association, aged 85 died December 24, of hypostatic pneumonia

William Albright Haman, Reading Pa Hahnemann Medical College of Philadelphia 1883, founder and chief of the x-ray department since 1916 charter member and chief of the medical department since 1892 Homeopathic Hospital aged 81 died suddenly, December 20, of coronary occlusion and arteriosclerosis

Herbert T Hames ☉ Jonesville S C Medical College of the State of South Carolina, Charleston, 1901 for many years a medical officer in the National Guard and at the time he was honorably discharged held the rank of captain aged 64 died January 4, in the Wallace Thomson Hospital Union of coronary thrombosis

Edward Mitchell Harding, Newton Mass College of Physicians and Surgeons, New York 1874 member of the Massachusetts Medical Society, at one time served as second assistant physician at the Danvers State Hospital Hathorne aged 90, died, December 19 of heart disease

Leo Zeno Hayes ☉ Force, Pa Medico Chirurgical College of Philadelphia, 1902 on the staff of the Andrew Kauf Memorial Hospital, St Marys formerly surgeon for the Shawmut Mining Company, and Pittsburgh Shawmut and Northern Railroad aged 64, died, December 20 in the Temple University Hospital, Philadelphia, of brain abscess

James Arthur Jones, Boston Boston University School of Medicine, 1900, formerly assistant instructor in urinary analysis at his alma mater, served as a medical officer in the Reserve Officers Training Corps during World War I aged 68 for many years on the staff of the Massachusetts Memorial Hospitals, where he died, January 1, of cerebral hemorrhage

Bertie Rozel Johnston ☉ Estill, S C University of Georgia Medical Department, Augusta 1917 served during World War I, aged 47, died suddenly, January 1, of coronary occlusion

John Richard Keesee ☉ Huntington, W Va Kentucky School of Medicine, Louisville 1905 served overseas and as captain in the medical corps of the U S Army during World War I aged 62 died, December 20 in the Veterans Administration Facility of hypertensive coronary arteriosclerotic heart disease

Joseph Charles Kelly, Boston McGill University Faculty of Medicine Montreal Que Canada 1938 began active duty as a lieutenant junior grade in the medical corps of the U S Naval Reserve in April 1942 and was discharged for physical disability in October 1942 served as clinical assistant in ophthalmology at the Massachusetts Eye and Ear Infirmary, aged 33 died December 17, of coronary occlusion

Valentine John Klein, Brooklyn University of the City of New York Medical Department 1887 member of the Medical Society of the State of New York on the staff of

St Catherine's Hospital, aged 76, died, December 28, of carcinoma of the rectum

Hiram L Knapp, Newark Valley, N Y, University of Buffalo School of Medicine, 1888, member of the Medical Society of the State of New York past president of the Tioga County Medical Society, had been a director and president of the First National Bank of Newark Valley for many years served as president of the village of Newark Valley and board of education, aged 75, died, December 21, of nephritis

Albert Maxwell Lightstone, Montreal, Que, Canada, School of Medicine and Surgery of Montreal, 1918, served as a captain in the Canadian Royal Army Medical Corps during World War I formerly registrar of the Woman's General Hospital, Westmount medical officer of the Montreal Sailors' Institute for many years, aged 55 died, December 11

Samuel Gilmore Logan Ⓢ Ridgway, Pa Jefferson Medical College of Philadelphia, 1901 past president and secretary of the Elk County Medical Society, member of the Radiological Society of North America Inc on the staff of the Andrew Kaul Memorial Hospital St Marys, physician for the Ridgway borough schools aged 65, was found dead December 21 of coronary disease

John Joseph Lucy, Boston, Harvard Medical School, Boston 1920 member of the Massachusetts Medical Society, aged 49 served on the staff of the Cambridge (Mass) Hospital and as assistant visiting surgeon on the staff of the Boston City Hospital where he died, December 28, of hypertensive heart disease

Harry Found MacLeod, Boston, University of Pennsylvania Department of Medicine Philadelphia 1894 served during World War I aged 71, died December 21, in the Holy Ghost Hospital for Incurables Cambridge, Mass, of cerebral thrombosis and pneumonia

Reed Madden, Xenia Ohio, Eclectic Medical Institute, Cincinnati, 1894, member of the Ohio State Medical Association served on the staff of the Ohio Soldiers and Sailors Orphans Home Hospital aged 72 died, December 26, of carcinoma of the prostate

Saul Marks, Philadelphia Medico-Chirurgical College of Philadelphia 1914 aged 48 died, December 20, in the Philadelphia General Hospital of coronary occlusion

Floyd Osborn Mathews, Charlemonst Mass, College of Physicians and Surgeons Boston, 1920, aged 52, died, December 15, of cerebral hemorrhage

Herbert Chamberlain Maxwell, Lubbock, Texas, University of Texas School of Medicine Galveston, 1916, member of the State Medical Association of Texas, physician for the Lubbock Independent School District since 1929 member of the staff of the Lubbock Sanitarium formerly on the staff of Dr Greenwood's Sanitarium, Houston aged 60, died recently of heart disease

Maurice Carver Melrose Ⓢ Independence Iowa State University of Iowa College of Medicine, Iowa City 1924, on the staff of the Peoples Hospital, aged 48 died, December 10, of hemorrhage due to hemophilia

Charles E Merriam, Rochester, Vt Baltimore Medical College, 1894 member of the Vermont State Medical Society aged 78 died, December 23, of auricular fibrillation

George W Neilson, Milwaukee Milwaukee Medical College 1909 member of the State Medical Society of Wisconsin at one time served as vice president of the Milwaukee County Medical Society formerly associate clinical professor of obstetrics and gynecology at the Marquette University School of Medicine, during World War I served as a major in command of a field hospital in France, aged 60 died, December 1 of heart disease

La Fayette Neufarth, Mount Healthy, Ohio Medical College of Ohio, Cincinnati, 1883, for many years president of the school board of Mount Healthy, aged 88, died, December 22 of pneumonia

Thomas Ignatius O'Drain Ⓢ Philadelphia University of Pennsylvania Department of Medicine, Philadelphia, 1893 aged 74 on the staffs of St Joseph's Hospital St Agnes Hospital and St Mary's Hospital, where he died, January 7, of a ruptured coronary artery

Isadore Olef Ⓢ Boston, Harvard Medical School, Boston, 1926 since 1939 assistant professor of medicine at the Tufts College Medical School where he had been teaching assistant in medicine from 1928 to 1930 and instructor in medicine from 1930 to 1939, on the staff of the Boston Dispensary and a member of the associate staff of the Joseph H Pratt Diagnostic Hospital, aged 45, died December 16, in Dorchester of coronary occlusion

Darbari Ram Pal Ⓢ Paterson, N J, University of Tennessee Medical Department, Nashville, 1911, during World War I received a special presidential citation for duties on local draft board, division 5, on the courtesy staff of St Joseph's Hospital aged 57, died, December 16, of essential hypertension

Fletcher Edward Peters, Defiance, Iowa John A Creighton Medical College, Omaha, 1904 aged 61, died, December 6, of myocarditis

James Milton Philpot, Bowling Green Fla Georgia College of Eclectic Medicine and Surgery, Atlanta, 1916 aged 57 died, December 21, in Immokalee of organic heart disease

John W Pinkston, Greenville, Ga Southern Medical College, Atlanta, 1889, member of the Medical Association of Georgia, aged 82 died, December 14, of cerebral hemorrhage

Heber Edward Robinson, Ogden Utah Jefferson Medical College of Philadelphia, 1906 member of the Utah State Medical Association, on the staff of the Dee Memorial Hospital, aged 62 died, December 9 in Livermore, Calif of cerebral hemorrhage and chronic undulant fever

Hendric Arnold Ross Ⓢ Arkadelphia Ark Jefferson Medical College of Philadelphia 1912 past president of the State Medical Board of the Arkansas Medical Society, owner of the Ross Hospital, aged 58, died, December 18 of coronary thrombosis

James Thweatt Ross, Macon Ga Jefferson Medical College of Philadelphia 1885, member of the Medical Association of Georgia for many years chairman of the city and county boards of health for many years on the staff of the Macon Hospital, served as chief surgeon for the Georgia, Southern and Florida Railroad aged 81 died December 22 of senility

Joseph Wilfrid Tetrault, Montreal, Que Canada School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1903, died in December

Frank Tornholm Wahoo, Neb Omaha Medical College 1902, member of the Nebraska State Medical Association, secretary and formerly president of the Saunders County Medical Society served as councilor from the Sixth District Medical Society for many years, was city physician and councilman in Wahoo for several terms, aged 72, died November 10 of cerebral hemorrhage

Jean Archange Vernier Ⓢ Detroit, American Medical Missionary College Battle Creek, 1900, formerly instructor of gynecology at her alma mater served as a member of the medical staff of the Women's Hospital, Detroit and the Battle Creek (Mich) Sanitarium, aged 68 died, December 21, of carcinoma of the stomach

James Buchanan Wallace Ⓢ Saline Mich, Detroit College of Medicine, 1901, member of the Michigan State Medical Society at one time a minister served as coroner of Washtenaw County, member of the board of education and health officer of Saline village and township, aged 78 died December 4 of diabetes mellitus

Cadow B Walling, Collins Ga University of Georgia Medical Department, Augusta 1902 member of the Medical Association of Georgia, physician and surgeon for the Seaboard Air Line Railway Company, aged 72 died December 13 in the Jelks Hospital, Reidsville, of Brills fever and pneumonia

Bureau of Investigation

SOME MISCELLANEOUS MEDICAL FRAUDS

A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of *THE JOURNAL*. Following are brief abstracts of some fraud orders not dealt with previously.

Consultorio Medico Standard—This was but one of numerous names used by M S Kemp or Kemps whose full name was said to be Samuel Kemp or Kemps and who operated a diabetes cure swindle from Mexico City. Other titles for his business were Instituto Medico Standard Clinica Medica Alemana Maria Asuncion Figueroa M A Figueroa Juan Rodriguez Sampedra J R Sampedra Dr R F Sanchez and Director S Kemps. The information that follows is taken partly from the records of the Bureau of Investigation of the American Medical Association and partly from the memorandum issued on this case by the Hon Vincent M Miles Solicitor for the Post Office Department. The concern in question first came to the attention of the Bureau of Investigation in December 1937 through an inquiry from a man in Texas. He wrote that as a diabetic patient he was interested in the promoters claim in a Mexican magazine advertisement: "Diabetes! Let me hear from you. I have cured thousands suffering from this malady—thousands here in Mexico and other Republics."

The inquirer said that on writing to the advertiser he received a history blank to fill out and a request for \$15 down and a second payment of \$10 when cured. As Dr S Kemps and his Instituto Medico Standard were unknown to the American Medical Association inquiries about them were sent to two American physicians practicing in Mexico City. In answering both implied that Kemps concern was a quack outfit and that part of it advertised as Maternidad—Clute 26 specialized in abortions. One stated: "For many years S Kemp (Samuel Kemp) ran the show alone pretending to be a German specialist but without Degree revaluated in Mexico. However for some time now to avoid legal difficulties he has associated with him a young doctor Fernando M E pinosa graduate of the Universidad de Cuadalupe in 1930 who does have his title registered with the Department of Health of Mexico. Unfortunately there are no laws in Mexico permitting revocation of license for improper advertising. It got so bad about a year or so ago that rulings were passed forbidding medical advertising and modified to require all advertising to be O K'd by a special department of the Health Department but that has remained a dead letter for apparently anything goes. The physician went on to say: 'I had a young medical student take in a sample of diabetic urine and try and get as much information as possible. He managed to have an interview with Doctor Kemps. This person is an Austrian and apparently without any formal medical education although he claimed to have studied all over Europe. My informant went several times and said there were always five or six or more clients in waiting but apparently the greater part of their work is done by mail. Kemp said it was not necessary for the patient to come in although it would be preferable and a k'd for a sample of urine which he sent to a laboratory. He made no mention of the necessity for blood examination. On seeing the laboratory report he guaranteed to cure the patient in three or four months. He used a medicine given by mouth a liquid mixture called D B T made especially for him by the Perez Gil Laboratories Calz Tlalpam 1557. He spends large amounts in advertising averages better than a column a day in the two daily newspapers (in each) and more than half a page on Sundays. He boasted of having a good many clients in the United States. The other physician wrote in part about Kemps: 'I do not know the nature of the treatment which he advertises for the cure of diabetes. There are two or three drugs derived from Mexican plants which are reported to have an influence on reducing the amount of sugar in the urine of diabetics and that probably have some slight beneficial effect on diabetics. The name of one of these is tencadora it is on the market under the name of glucocina. The botanical name of this plant is tecomanolis. Another is called copalchi and the botanical name of this plant is contrarea latiflora. Finally the Post Office Department at Washington began to investigate Kemps business and found that the man was advertising in various Spanish language newspapers printed in the United States and offering cures for diabetes liver trouble and sexual debility. In a test case the customer sent \$15 by United States money order for treatment of lost manhood. With his reply Kemps sent a short prescription in which it was suggested that for the treatment and cure of his condition the remitter take one tablet of calcium phosphate before meals three times a day and one tablet of nux vomica two hours after meals three times a day. These preparations were to be purchased by the customer from his local drug store. Since medical evidence available to the Post Office showed that the condition loosely described as lost manhood is due to a large number of causes such as advanced years psychic influences and many diseases including some serious ones and that each victim of it must be treated as an individual case and further since Kemps treatment was based on no diagnosis whatever the business in question was declared to be a scheme for obtaining money through the United States mail by means of false and fraudulent pretenses representations and promises. The fraud order debarred it from the United States mails was issued July 15 1942.

Dynell Spring Water Company—This concern had for its president a Charles A Coe who for at least twenty years has been exploiting the water of his so-called Dynell Springs in the southwest section of Chicago and at times has played it up in large newspaper advertisement. In a discussion of this business published in *THE JOURNAL* Sept 15 1928 page 818 it was brought out that Coe had previously engaged in various enterprises such as trucking livery business and a so-called school of motoring and had solicited the public to buy stock in his Dynell concern. The claims that he has made for the water as a treatment for a great variety of diseases and conditions came to the attention of the Post Office Department which on May 9 1942 ordered Coe and his company to show cause on May 28 why a fraud order should not be issued against them. On May 27 the defendant's attorney requested a postponement of the hearing date giving as one reason the alleged fact that his clients were attempting to dispose of the enterprise and with draw from the mail order business and the attorney was furnished a form of affidavit containing provisions for the abandonment of the claim and informed that if this affidavit was duly executed by the defendant and filed with the Post Office it would be accepted as a basis for disposing of the fraud order charges. At the same time the hearing date was continued at the request of counsel. Thereafter the same counsel for various reasons requested numerous postponements some of which could not be granted and the hearing finally took place on July 31. No appearance however was entered by anyone in behalf of the Dynell concern nor was any answer to the charge received. A few days thereafter a transcript of the proceedings of the hearing was given to the respondent's attorney and an opportunity was furnished him to file a brief on or before August 17. At his request he was granted at least two additional postponements but in spite of his promise to furnish certain affidavits this was not done. At the original hearing the Post Office reviewed the charge that Charles Coe had advertised his product variously called Dynell Water Dynell Mineral Water and Dynell Spring Water under false and fraudulent pretenses representations and promises among which were that it is an effective treatment for and will overcome diseases of the liver gall ducts and gall bladder arthritis rheumatism arterio sclerosis high blood pressure diabetes kidney trouble stomach ulcer stomach trouble nephritis and all diseases of the genito urinary tract strikes the death blow to the cause of most diseases. A chemist who appeared as a witness for the government testified that his analysis disclosed that Dynell Water contained silica ferric oxide or aluminum oxide calcium magnesium sulfate chloride sodium bicarbonate radical calcium bicarbonate potassium and nitrate. Also appearing for the government was a physician who testified that he was familiar with the therapeutic effect of these various ingredients all well known to the medical profession and that the principal effect of the water in question when taken as directed would be a tendency toward laxation due principally to the presence of magnesium sulfate and it would also have a slight neutralizing and antacid effect because of the calcium bicarbonate present. He went on to show that the water did not have any significant effect on the various diseases and other conditions played up in the advertising. On Sept 8 1942 the Post Office Department issued a fraud order against the names Dynell Spring Water Company Dynell Spring Water Co Dynell and C A Coe President and debarred them from using the mails. In passing it is worth mentioning that an interstate shipment of Dynell Water in 1928 was declared in a district federal court to violate the Food and Drugs Act because of the false claims made for the product as a treatment of chronic constipation ulcerated stomach torpid liver high blood pressure rheumatism gastritis neuritis gout gallstone Bright's disease diabetes and some other things.

International Health Device Corporation and David B Cropp—In this department of *THE JOURNAL* April 4 1942 page 1240 appeared a lengthy report of a fraud order issued by the Post Office Department against the Pandiculator Company and Henry C Crowell of Cleveland in the mail order sale of The Pandiculator. This was an alleged spine stretching device which had been on the market for a good many years. At the hearing of this case Crowell a Cleveland attorney had testified that he had purchased the business in 1918 from a David B Cropp. It appears that Cropp in due time resumed the sale of the Pandiculator but adopted another name for his business and his device. It came to the attention of the Post Office Department that Cropp operating under the name The International Health Device Corporation at New York was putting out something known as the Therapeutic Couch or the Cropp Therapeutic Couch the description of which seems to correspond with that of the Pandiculator. Per on who answered his advertisements received a booklet *The Human Body* which according to the Post Office played up the alleged efficacy of the device in stretching not only the spinal column but the entire skeleton the bony framework of the body involving all its joint and articulation. The musculature the ligaments cartilages and other connective tissues the spinal cord the spinal and sympathetic nervous system the blood vessels arteries glands lymphatic in short every important structure of the body and every functioning organ comes within the direct influence of the Science of Tension Therapy as applied through the Cropp Therapeutic Couch.

We do not offer the Science of Tension Therapy and the Therapeutic Couch as a panacea a cure all for the ill of mankind. We do offer it as a Therapy separate and distinct in itself. It is the most rational and universally applicable means of removing the basic causes of disease all health and physical imperfection with which we are familiar. We believe that there is no method either of medication or of hand adjustment for the correction of diseases and abnormal conditions of the body that can so easily be employed by 100 per cent of suffering humanity with so certain likelihood of definite permanent benefit as can Tension Therapy and the Therapeutic Couch. In addition to the booklet Cropp was said to have issued a circular which repeated alleged testimonials from laymen osteopaths chiropractors and physiotherapists as to the efficacy of the couch in treating such disorders as stomach ailment rheumatism neuritis diabetes arthritis a

numerous others and also in increasing height and reducing bodily weight and waist line measurements. On Dec 10 1941 the Post Office Department notified David B Cropp and the International Health Device Corporation to show cause on Jan 6 1942 why a fraud order should not be issued against them. After several continuances the hearing was finally held on March 18 and 19. Cropp appeared unaccompanied by an attorney and in his testimony stated that he was not a physician but had studied chiropractic that his couch was safe and harmless and would accomplish the results claimed for it in the advertising. It was reported that he appeared to be in good health and did not look his sixty six years of age and although he had led a life devoted almost exclusively to athletics he attributed his physical soundness to the use of his couch which opinion was discounted by the government.

An expert medical witness for the Post Office testified at length showing that Cropp's mechanism was without virtue as a corrective curative or restorative agent and that the only effect it would produce when used as directed would be the stretching of the body on a straight line parallel to the spine the amount of stretching being dependent on the amount of pressure placed on the wheels at the side of the couch by the patient. It would not be testified cure or correct any disease and in fact it might aggravate some conditions such as tuberculosis of the spine by the application of traction. On Oct 3 1942 a fraud order was issued against the names David Cropp David B Cropp and the International Health Device Corporation and their officers and agents. In one part of the Post Office memorandum Cropp was called Bertram David Cropp and described as formerly a director of physical education and athletics at the University of Colorado and presently the wrestling coach of the West Side Y M C A at New York.

DANGEROUS TO HEALTH

Because of Inadequate Warnings on Labels

[EDITORIAL NOTE—These abstracts differ from other abstracts of Notices of Judgment issued by the Food and Drug Administration of the Federal Security Agency which have appeared in these pages in that they deal with nostrums which were misbranded because their labels failed to carry adequate warnings against giving them to children or using them in those pathologic conditions in which they might be dangerous to health, or caution against unsafe dosages or methods or duration of administration or application, for the protection of the user. The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Hart's Compound Asthma Medicine—Hart's Asthma Medicine Company, Buffalo, N. Y. Two consignments shipped respectively between March 15 1940 and Jan 13 1941 and on Feb 26 1941. Composition essentially 64 grains of potassium iodide per fluid ounce with glycerin water and flavoring materials including cinnamon and cardamom. Adulterated because it consisted in part of a filthy substance namely mold. Misbranded because label failed to warn adequately against giving it to children or using it in those pathologic conditions wherein it might be dangerous to health or to caution against unsafe dosage or methods or duration of administration or application for protection of users. Further misbranded because label falsely represented that it was efficacious in treating asthma including the relief of paroxysms or spasmodic attacks, bronchitis, colds and hay fever and that it would preserve health.—[D D N J F D C 459 and 460 September 1942.]

National Pepple's Remedy—National Pharmaceutical Manufacturing Company, Baltimore. Shipped June 20 1940. Composition chiefly extracts of plant drugs including aloe. Misbranded because label did not carry adequate directions for use or sufficient warnings against employment in those pathologic conditions wherein it might be dangerous to health or caution against unsafe dosage or duration of administration for protection of users. Further misbranded because label failed to bear the common or usual name of each active ingredient.—[D D N J F D C 450 September 1942.]

O. D. Easy-lax—Washington Wholesale Drug Exchange (seller) and Liberty Drug Company, both of Washington, D. C. Label instituted Jan 9 1941. Composition essentially phenolphthalein, aloin, strychnine, talc and calcium carbonate with green coloring. Misbranded because label did not adequately warn against use by children or in those pathologic conditions wherein it might be dangerous to health or caution against unsafe dosage or methods or duration of administration. Also misbranded because label carried such false claims as "They work naturally and form no habit." A home remedy for indigestion, torpid liver, chronic constipation. Further misbranded because common or usual names of active ingredients were not given on label or a declaration of the quantity or proportion of strychnine present and because carton and label failed to give the address of the manufacturer, packer or distributor and the label to declare the quantity of contents.—[D D N J F D C 451 September 1942.]

Correspondence

"THE SUPPLY OF NURSES"

To the Editor—I trust that in view of the present acute shortage of nurses you may be able to publish this and that some hospital executive may consider and develop the plan.

When serving in the Militarized Red Cross overseas during the last war, I was assigned as an assistant surgeon to a small English hospital for French wounded, situated not far from Chaumont. I was there from April or May 1917 to January 1919. Then, as now, there existed an acute shortage of trained nurses. Yet the work of the hospital went on at all times smoothly and well in spite of this. The hospital director was a most forceful English woman with executive ability from whom I learned their methods of action. Our nursing force was composed of a trained head nurse, an operating room nurse and one or two other graduate nurses. The remainder were short term, intensively trained volunteer nurses. We got wounded, often direct from the front. These assistant nurses, in operating room, dressing and ward work, did their stuff well, judged by peacetime standards. Those appointed as heads of wards were resourceful and efficient.

I believe I had seen the best of trained nurses both here and abroad and so could judge nurses, for my experience had covered an internship of sixteen months in a New York hospital that employed exclusively recent graduates of training schools, an internship of three months in another, employing selected groups of pupil nurses from the New York, Presbyterian and St. Luke's hospitals, and from then until World War I in contact with surgical procedure both in Hartford and through visits to outside surgical centers. I served in Dr. Blake's Hospital in Paris in 1917 to require the then "war surgery."

The following is what I learned from the director and others concerning the composition of this group of nurses in France: 1 All were young women. 2 All volunteered to serve wherever ordered. 3 They were selected for high standards of conduct, physique and patriotism. 4 They were intensively trained surgically, in leading hospitals chiefly in London. 5 The term of training was four or six months. I am not certain which now, but my impression is four months. 6 All those that came to us had been again checked over by the sister of our director and the last desirable screened out before they sailed. By this process we got a body of nurses that for surgical work was adequate. And I feel confident that a skilled onlooker could not have distinguished them in work or deportment, if similarly garbed, from a body of trained nurses.

This method of overcoming a shortage of trained nurses in another war makes me believe that a similar procedure would give equal results today. However, there is no royal road to excellence in any field, and I fancy that the selection and training of a body of nurses such as I describe would prove an undertaking worthy of any one's best effort.

JOHN B. MCCOOK, M.D., Hartford, Conn.

MAXIMUM DOSAGE OF INSULIN

To the Editor—In the editorial on "Insulin Resistance" (THE JOURNAL, January 2, p. 52) reference is made to the fact that a patient received 3,250 units of insulin during a period of twenty-four hours. It is commented that this was probably the largest amount of insulin ever administered to a human being.

Merely for purposes of record, may I refer to a report (Lozinski, Ezra, and Frohlich, Louis I. Resistance to Insulin. *Canad. M. A. J.* 46:62 [Jan.] 1942) in which is recorded the history of a patient to whom 5,780 units of insulin was administered in a period of twenty-four hours without the development of hypoglycemic shock.

EZRA LOZINSKI, M.D., Montreal.

Bureau of Legal Medicine and Legislation**MEDICOLEGAL ABSTRACTS**

Malpractice Sponge Allegedly Left in Bladder in Repairing Prolapsed Uterus—The plaintiff was suffering from a prolapsed uterus, rectocele and cystocele and the physician defendant undertook surgical procedures for the purpose of suspending the uterus Two incisions, both about 1½ inches long, were made in the vagina one in the anterior and one in the posterior wall The uterus had dropped into the vagina, but, according to the physician, it 'didn't come clear outside', the rectum and the bladder came outside' The bladder was down as low as the uterus and "was protruding through the vaginal wall" The physician had to work close to the bladder wall, which was quite thin, but, so he testified, he did not cut the bladder According to the patient, subsequent to the operation the physician told her that he "had had to build up a new bladder wall"

Some time after the operation the patient began to experience pain in the bladder A roentgenogram showed a "big rock in the bladder with a little tail on it" About twenty-one months after the first operation another physician removed the stone from the bladder Incorporated in the stone on one side was a mass of cotton gauze Alleging that the physician had negligently left the gauze in her bladder during the first operation, which was the only operation to which she had ever submitted prior to the operation for the removal of the stone in her bladder, the patient brought suit for malpractice against the physician defendant From a judgment for the patient, the physician appealed to the Supreme Court of Oregon

The physician claimed that during the operation in question he had neither cut the bladder nor inserted any gauze in the bladder Therefore, so his argument seemed to run, there was no evidence before the trial court to sustain the patient's allegation that the gauze had been left in the bladder by the physician defendant, and the trial court should have granted the motion he had made for a nonsuit or for a directed verdict in his favor In passing, said the Supreme Court, on the propriety of denying a motion for a nonsuit or for a directed verdict for the defendant, one must take as true, even in the face of conflicting evidence the evidence produced by the plaintiff together with every inference of fact that the jury might legally draw from it The evidence at the trial tended to show that the bladder was exposed that a new bladder wall was built up, that cutting was done, that gauze sponges were used in the operation and that a gauze sponge was removed from the patient's bladder twenty-one months later The patient was entitled to show, as she attempted to do by the evidence she introduced, that the physician had had an opportunity to leave a gauze sponge in her bladder and that he was the only one who could have done the act charged If the jury believed the evidence introduced by the patient, as it apparently did, it was justified in finding that gauze was placed and remained in the plaintiff's bladder and that the physician had an opportunity and was the only one who did have an opportunity to place it there and therefore that the defendant did the act charged

Furthermore, continued the court there was ample evidence concerning proximate causation and damage There was evidence from which the jury was justified in finding that gauze was inserted by the defendant in the bladder and allowed to remain there, that in so doing he was negligent and that as a result a condition developed that caused infection and pain and required operative intervention No question of liability for a

mistake of professional judgment was involved. It was not claimed that the gauze should have been inserted in the bladder or that, if inserted, the removal of the gauze at the time of the operation would involve any exercise of professional judgment, or that any incision of the bladder wall should have been made. The whole defense of the physician was that he had made no incision in the bladder, that he had not inserted any gauze in the bladder and that consequently no gauze had been left therein by him. The physician was not employed to enter the bladder, and no necessity to do so was shown. If he did so, even intentionally, his act would be an unauthorized deviation from his employment. On the other hand, an unintentional incision of the bladder would be evidence of negligence. While some courts have held a physician negligent as a matter of law on evidence that he inserted gauze in and failed to remove it from an incision, the court did not believe that the failure to remove sponges is in all instances negligence on the part of the physician. The court did believe, however, that evidence of failure to remove sponges does require the submission of the question of negligence to the jury, since it is *prima facie* negligence for an operating physician to leave a surgical sponge in a wound after the incision has been closed. 41 *Am. Jur.*, p. 213. A different situation might be presented if the placing of a sponge in the bladder had been shown to be proper and the question had arisen only as to the propriety of its removal, but where the defense is that no sponge was inserted the fact, as found by the jury, that one was inserted and permitted to remain, no good purpose therefor appearing, raised a *prima facie* case of negligence. The court therefore concluded that the trial court had properly refused to grant a nonsuit or to direct a verdict in favor of the physician.

During the trial a medical witness called by the plaintiff was asked to assume that in the course of an operation for the suspension of a prolapsed uterus the operating physician placed and left gauze in the patient's bladder and to state whether in that event the physician exercised that degree of care and skill ordinarily used and exercised by physicians in the practice of surgery in the locality and under the circumstances. The witness answered in the negative. The physician contended that the question was improper because 'it assumed an absolute fact that the operating physician had cut the bladder and placed gauze therein "when the evidence along that line was clearly speculative and conjectural." It is the peculiar function, said the Supreme Court, of the hypothetical question to assume as an absolute fact alleged conditions or events if supported by evidence and to have an opinion based on the hypothesis. The patient, in forming the hypothetical question, should not leave to speculation the facts on which the opinion was to be based. If the plaintiff asks a fair question based on substantial evidence, he may have the expert's opinion on any combination of facts he may choose. He need not include in the question all the details that appear in his own case and certainly cannot include the contradictory matter in his opponent's case. He may lay before the jury by hypothetical questions scientific inferences properly deducible from the facts supported by his evidence. The form of such questions is generally within the discretion of the trial court. The court concluded accordingly that it was proper for the trial court to permit the question propounded.

The physician next complained of certain instructions tendered by the trial court to the jury which, so he contended, stressed the question of ordinary care, ordinary skill and ordinary diligence. While such an instruction is proper in the ordinary negligence case, he insisted, since a malpractice action is not the ordinary negligence case, that such an instruction is clearly erroneous in a malpractice case in which the measure of care is that degree of care and diligence ordinarily and usually exercised by ordinarily careful physicians and surgeons under like circumstances and in similar localities. In ordinary negli-

gence cases, so his argument went, the test is the conduct of the ordinary prudent man under the circumstances and "that a man has acted according to his best judgment is no defense while in a malpractice action the fact that want of success is due to an error of judgment may sometimes be a defense. Even so, answered the court, in this case there was no question concerning the exercise of professional judgment, mistaken or otherwise, so far as the placing or removal of a sponge was concerned. The defendant cannot claim now that he made a mere error of judgment in failing to remove a sponge which he swears he never inserted. If the instruction of the trial court applied to this case the standard of care applicable to ordinary negligence cases, then the instruction was unduly favorable to rather than prejudicial to the physician who was under obligation to exercise that degree of skill, care, diligence and knowledge which is ordinarily possessed by the average of the members of his profession in good standing in similar localities. But continued the court, the jury was properly instructed concerning the defendant's duty as a surgeon. After explaining what negligence ordinarily consists of, the instruction complained of stated that ordinary care in a malpractice action means the care imposed by the law on physicians and surgeons, and the court then said, "by that standard will you measure the responsibility of the defendant in this case?" The court could not properly have stopped with a mere definition of negligence as in ordinary negligence cases. It was necessary to go further and apply that general concept of ordinary care to the case of a physician but in truth the duty of care imposed on physicians and surgeons is only a special application of the general law of negligence requiring due care under the circumstances. In malpractice the circumstances are peculiar, and so the general rule is peculiarly adapted to meet them. Among the circumstances are the skill and training of the physician, the inherent difficulties of operative treatment, the impossibility of certainty in diagnosis and cure and the frequent necessity for the exercise of professional judgment, together with the advanced condition of the medical science in the community. In *Staloch v. Holm*, 100 Minn. 276, 111 N. W. 264, a case cited by the physician, the court, after explaining that a physician is not liable for a mere error in judgment, made the following distinction:

When the physician is actually operating he is employing surgery as an art and if for example he sews up a sponge in an abdomen he has opened his wrong concerns physical fact and has fairly been held to be governed by ordinary principles of negligence.

The use and removal of surgical sponges continued the court in operative cases may involve the employment of professional skill, but the failure to remove a sponge which should never have been inserted would be evidence of negligence in the general sense that it would involve a failure to exercise reasonable care under all the circumstances. A fortiori, it would be evidence of negligence when subjected to the test employed in the case of physicians and surgeons. The court accordingly held that the instructions complained of were proper.

The judgment in favor of the patient was affirmed.—*Caruthers v. Phillips*, 131 P. (2d) 193 (Or., 1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore

Studies on Rh Agglutinin of Human Blood—Fisk and Foord performed tests for the Rh factor of the blood of 927 adults, of 312 infants and of 9 cases of fetal erythroblastosis. The tests were run with anti rhesus and/or human anti Rh serums. The anti rhesus serums were prepared by immunizing guinea pigs with rhesus monkey blood. The human anti Rh serums were obtained from Rh negative women who had delivered infants affected with erythroblastosis. The results of typing adult blood with the antisera show that the incidence of Rh positive persons was 85 per cent and of Rh negative persons 15 per cent. This agrees with the observations of Landsteiner and Wiener, who reported 15.4 per cent of 448 persons to be Rh negative. The results also suggest no relationship between the presence of the Rh factor and agglutinogens A and B. The results with cord blood compared with adult blood showed a consistent difference in reactivity to guinea pig antisera: the cord blood from the 312 infants reacted positively to these serums, whereas the reactions to two other serums supplied by two Los Angeles hospitals gave a percentage of negative reactions. Of the 191 infants typed with the human anti Rh serum, 10.5 per cent were Rh negative. The degree of agglutination in guinea pig antiserum was always much stronger with cord blood than with adult cells. It was at first suspected that these strong reactions were due to some property in the cord blood which was not altered by repeated washings in saline solution but this seemed unlikely as blood obtained by heel puncture from 9 babies on the tenth day of life reacted in the same way.

Burns Treated by Paper Tissue—Callahan states that an infected (or uninfected) burn treated by free cleansing with soapy sterile water debrided, dried covered directly by cod liver oil ointment and this covered by a single layer of paper tissue and redressed daily, then less frequently as required, and kept in daily motion will heal in a minimum of time with a minimum of pain and scar formation without contracture. Good surgical measures must be used. Blebs are left intact unless they break in cleansing, as then less open wound is present and less tender surface is exposed. Serum under a clean bleb does not become infected, it acts as a cushion conducive to healing, and it is reabsorbed or spills harmlessly if its covering is kept clean. Maxmow showed that noncontaminated tissue bathed in its own fluids healed with rapidity and a minimum of fibroblast proliferation in the scar. To this end Callahan has used a covering that is nonadherent is completely flexible and allows a free film of normal fluid beneath it. Elevation of the burned part and daily motion prevent and minimize stasis as well as act as a prophylactic toward circulatory accidents, thrombi or emboli. Nonadherence and motion permit granulation or epithelialization across the affected area that will not require stretching or breaking in subsequent therapy. The paper tissues packed in their usual store shelf manner are safe to use, although the author does autoclave or flame them. He used them for lesions many years before he autoclaved them and no infection has resulted. Blood agar plates and culture broths of newly opened commercial cod liver oil ointments revealed no growths from the surfaces or the depths of ointments. Such

data show that the paper tissue and the ointments are safe to place and use in the field, or board ship, in a home, in a hospital and in the physician's office

The Tuberculous Obstetric Patient F M Meixner Peoria—p 454
Psychotherapy in General Medicine and Surgery T B Throckmorton Des Moines Iowa—p 460

Kaolin-Aluminum Gel and Peptic Ulcer—Neuwelt and Steigmann used a mixture of aluminum and kaolin (Kalam) in the treatment of peptic ulcer in 25 cases. Kalam is an amphoteric gel containing 5 per cent of aluminum hydroxide and 3 per cent of kaolin, both in colloidal form flavored with oil of peppermint and freely miscible in water. The subjects were refractory to other treatment. The dose of the amphoteric gel varied from 1 to 2 teaspoons in a little water three times a day to as much as 4 teaspoons taken as often as every two hours during the day and as needed at night. Some patients used the preparation for several weeks whereas others used it intermittently or steadily for many months of the eighteen months of the study. Six of 15 patients under prolonged and careful observation were decidedly and quickly benefited by the medication, pain, discomfort and vomiting were relieved promptly. The 9 remaining patients found the results indifferent; only 3 of them preferred some other form of therapy. From the results the authors conclude that Kalam represents a new and valuable addition to the therapy of peptic ulcer.

Metabolic Effects of Sex Hormones—Knowlton and her colleagues describe certain of the metabolic effects of estradiol benzoate when given intramuscularly in daily doses of 5 mg

(30,000 rat units) to 2 eunuchoids, 2 women with ovarian insufficiency, 1 of whom was masculinized, and 1 normal woman. In the 2 eunuchoids the effects are compared with those resulting from 5 mg daily of testosterone propionate. The subjects were given weighed diets, containing the same food each day, of sufficient caloric content to maintain their weight in accordance with the particular individual's activity, desires and capacity. Testosterone propionate caused a characteristic reduction in urinary nitrogen, inorganic phosphorus, sulfate and sodium excretion. In 1 of the 2 eunuchoids, urinary potassium was reduced. Creatinuria, when sustained at high levels by creatine ingestion, was reduced by the androgen. The production of basal heat was unaltered. The estradiol benzoate in the 2 eunuchoids, 1 hypogonadal woman and the normal woman reduced the urinary nitrogen, inorganic phosphorus and sodium excretion. Urinary sulfate was probably reduced in 1 eunuchoid and in the woman; otherwise it was unaffected. Creatine excretion in the eunuchoid, when sustained at high levels by creatine ingestion, was not reduced by estradiol benzoate. Basal heat was unaltered. In the masculinized girl (adrenogenital syndrome) none of the usual metabolic effects of estradiol benzoate were observed. Creatinuria was increased. Hypogonadal women of short stature and with high urinary gonadotropin titers responded well to the metabolic influences of estradiol benzoate or testosterone propionate. It is not clear whether physiologic ovarian secretion exerts any general metabolic influence on non-genital tissue.

Creatinine Excretion and Obesity—The results of creatinine determinations on 50 normal women from 20 to 45 years of age are tabulated by Tager and Kirsch. From this tabulation they derived expressions for the relationship of creatinine excretion to weight in normally proportioned and in obese women. The optimal weights, as calculated by the method of Willoughby, were further correlated with the actual values of the creatinine excreted for the 50 women. This optimal weight is defined as creatinine optimal weight. For a known level of creatinine excretion by a given patient (whether obese or not) the optimal weight of the patient may be determined by the application of the equation for creatinine weight relationship established for well proportioned women. In the absence of an actual laboratory determination the creatinine excretion and the creatinine optimal weight may be calculated through a conversion equation from the Willoughby optimal weight estimation, based on bone measurements. The creatinine optimal weight is closely compatible with clinical weight evaluations and offers a physiologic basis for the quantitative expression of the nutritional state of the adult woman. Obese women generally excrete less creatinine than the well proportioned ones and show more striking variations in the excretion levels from one individual to another at a given weight. These variations are generally in direct agreement with clinical impressions concerning the muscularity of the obese. The desirability of clinically differentiating overweight individuals on the basis of muscle mass into the macro-somic and meso-somic types is suggested to facilitate further metabolic studies in obesity.

Curare in Convulsive Shock—Since January 1940 Woolley and his associates have administered convulsive metrazol or electric shock therapy, with rare exceptions, only after patients were adequately curarized. Of 38 patients (all other methods of treatment having failed) treated with curare-metrazol shock and/or curare electric shock, 8 have recovered to their pre-psychotic level or better, 7 are now on parole status inside or outside the hospital, 4 are slightly improved in hospital adjustment and 19 are unimproved or worse. Curare is administered intravenously, approximately 11 mg per kilogram of body weight. From thirty to one hundred and twenty seconds should be taken for the injection. Maximal curarization occurs regularly between one hundred and fifty and two hundred and ten seconds after a slow intravenous injection and in thirteen to fifteen minutes after an intramuscular injection. Even if curarization is not complete (arbitrarily determined by the inability of the patient to lift his head) the severity of a convulsion is much modified by the presence of any considerable amount of curare in the circulation. Curare was effective in preventing physical injuries to patients subjected to convulsive shock therapy. It probably increased slightly the required dose of the convulsive agent. It introduces certain hazards, particularly in respiratory embarrassment or failure, but these can be avoided by proper management. Even when the patient is in serious difficulty from respiratory failure, artificial respiration, prostigmine and epinephrine are effective in preserving life. It does not seriously affect the blood pressure and heart action. In proper dosage, properly administered, it is quite safe to use. The results of treatment protected by curare are comparable to those without it.

Optic Atrophy from Arsenicals—Longley, Clausen and Tatum tried to determine whether atoxyl, and the contributing agents tryparsamide, arsenical number 190 and acetarsone are capable of producing blindness in monkeys with an intact and normal central nervous system. The eyes of rhesus monkeys resemble the human eye far more closely than those of the rabbit. Such an anatomic relationship might be expected to be paralleled by a similar reactivity but experimental work can only suggest what might happen in man and only careful clinical

study will reveal what actually does happen. The administration of atoxyl, tryparsamide, acetarsone, 3-amino-4-beta-hydroxy-ethoxy-phenylarsinic acid (number 190) and 4-beta-(beta-hydroxy)ethoxy-ethoxy-phenylarsinic acid (number 266), the last containing no nitrogen in the molecule, did cause blindness in monkeys. The work provides an experimental basis for detecting the blinding potentialities of arsenical compounds in man. Now prophylactic procedures designed to reduce or eliminate optic atrophy as a sequence of chemotherapy of neurosyphilis must be looked for.

Comparative Activity of Sulfonamides—Marshall and his colleagues compared the therapeutic activity of thirty-three typical sulfonamide compounds on streptococcal and pneumococcal infections in mice. With the exception of sulfapyridine, none were found to be significantly more active than sulfanilamide against streptococcal infection while most of them were less active. On a pneumococcal infection sulfapyridine, sulfathiazole, sulfadiazine, sulfamethylthiazine, sulfapyrazine and sulfaguanidine were all more active than sulfanilamide. All compounds which were active *in vivo* were also active *in vitro* and there appeared to be no quantitative relation between *in vitro* and *in vivo* activity.

Hematogenous Interstitial Nephritis—In 7 cases of renal suppression due to hemoglobinuria (blackwater fever in 3 and hemolysis due to drugs in 4) it was not always possible, according to Mathews to relate the interstitial inflammatory reaction to areas with tubular damage. The distribution of the exudate in the subcortical and cortical zones suggested, for the most part, that it was secondary to tubular damage. However cellular extensions along the interlobular vessels in the cortex, cellular foci and edema in the pyramids in some of the cases appeared to have developed as an independent process. Oliguria and anuria not due to ordinary forms of renal disease, low blood pressure or dehydration may be encountered in a variety of infectious states, hepatic necrosis and excessive intravascular hemolysis. The suppression may terminate spontaneously in diuresis and recovery or may end in death from uremia. In fatal cases the kidneys are usually swollen and show the structural changes of acute interstitial nephritis. Morphologically the condition is characterized by the interstitial lesion, and while its degree may vary, there are no structural details of the exudate itself that distinguish the disease processes of which it is a complication. The lesion is a structural manifestation of hyperergy in hemolytic streptococcus infection and is believed to have the same significance in interstitial nephritis associated with excessive intravascular hemolysis and hepatic necrosis. The theory that renal insufficiency in hematogenous interstitial nephritis is a functional manifestation of a hyperergic reaction has the advantage that it covers the full scope of functional abnormalities that might be concerned in the production of suppression and it is reasonably well supported by the structural changes and clinical facts.

Hyperactive Carotid Sinus Reflex—A case of the vagal bilateral type of hyperactive carotid sinus is presented by Gail in which an electrocardiogram made during mechanically induced syncope revealed prolonged ventricular asystoles ranging up to 38 seconds and auriculoventricular blocks. This disturbance of cardiac action resulted in cerebral anoxemia which caused syncope. Atropine sulfate abolished the cardiographic and clinical signs of carotid sinus sensitivity, thus establishing the diagnosis and therapeutic criteria of the case.

Choline Chloride and Icterus Gravis Neonatorum—Davis and Anderson studied the fat metabolism of 3 infants with icterus gravis neonatorum with a favorable outcome and the morphologic changes of 4 infants who died. During the course of the disease the prothrombin time of 2 infants was abnormally high. Bile salts 1 to 2 grains (0.06 to 0.13 Gm) daily with vitamin K were administered, but this did not alter the prothrombin time. Vitamin K hypodermically failed to reduce the prothrombin time, suggesting that the abnormal prothrombin time was not dependent completely on the absorption of vitamin K. Because of the close relationship between fat metabolism and vitamin K it seems possible that faulty fat metabolism in the liver prevents normal prothrombin formation. Microscopic study of the liver of babies dying of icterus gravis showed fatty infiltration and hemopoietic activity. It is believed that the choice of choline chloride that was added to a special feeding formula of the infants that recovered was effective in their cure. It appeared that the rate of recovery was definitely accelerated by the choline. An infant so treated but not completely recovered died after pneumonia developed. Although clinically typical, postmortem examination revealed a normal liver and spleen without fatty deposits. Therefore it appears that a diet of vegetable fat supplemented by labile methyl containing choline chloride and labile methyl containing casein is indicated for treating the faulty fat metabolism found in the hepatic dysfunction of icterus gravis.

Mortality from Malaria—In 1900 the death rate for malaria in the census registration area of the United States was 7.9 per hundred thousand. Under the vigorous antimalarial procedures then instituted the rate declined to 3.9 in 1905. From 1905 to 1937 the rate fluctuated from 3.8 to a minimum of 1.9 in 1926, without much change in the general trend. The statistics for 1938, 1939 and 1940 show such a significant change in the trend that Nichols presents them. For 1938 the death rate was 1.8, for 1939 it was 1.3 and for 1940 it was 1.1. The annual mortality for the entire period 1930 to 1940 shows that since 1937 there has been a sharp and continued decrease in mortality from malaria in the United States. This suggests that new conditions antagonistic to the disease have been established. The most obvious explanation for the decrease in mortality is that it was the result of the energetic and extensive antimalarial measures that were being carried out in the South, where most of the deaths from malaria in the United States occur.

Partial Heart Block Due to Digitalis—The series of 170 cases of partial heart block were obtained by Campbell from the ten thousand consecutive electrocardiograms taken at Guy's Hospital from 1927 through 1938. There were 141 cases with a prolonged PR interval but no higher degree of block and 29 who also at times had partial heart block with dropped beats. In 26 of the 170 treatment with digitalis was the sole or the important cause of the block and in another 6 it was the probable cause. In those with partial heart block and dropped beats and in those with latent heart block the PR interval averaged 0.21 second. In only 3 of 23 was the PR interval below 0.18 second. When there were no dropped beats the PR interval was on the average increased to 0.26 second. When there were dropped beats there were most often two responses before the dropped beat and the lengthening PR intervals averaged 0.22 second, 0.37 second, dropped beat and the like. This was the average of very varied figures. No special difference could be found between the groups with these different responses. Apart from the presence of latent heart block the etiology of the underlying heart disease did not seem of importance, though congestive failure was usually the indication for digitalis. The presence of a concurrent infection seemed the next most important factor. When there were dropped beats, more than half of the patients had some active infection. With latent heart block active infection was present less often, but it was the cause in a few. Large amounts of digitalis were rarely the cause. In general there seemed to be no severe ill effects even with dropped beats, and the block passed off within two or three days. There seems no reason why the presence of a latent heart block should prevent adequate treatment with digitalis when indicated, but the patient must be watched more carefully than usual.

Blood Pressure and Old Age—Howell determined the blood pressure of 120 Chelsea pensioners all veterans of the British army, aged from 65 to 92. Weekly variations of pressure, within narrow limits, were frequent. Infections especially those present with diarrhea or prolonged pyrexia almost always caused a fall in blood pressure. Three main types of blood pressure were observed. The first was of those whose systolic pressure remained above 160 mm. This was classed as raised blood pressure and included 42 per cent of the total persons. The second was of those with a systolic figure below 160 but above 115 mm and the third was of those with a systolic pressure below 115 mm and included 5 per cent of the total. Although the grouping is arbitrary it did correspond with certain clinical classes. Cancer, cardiac failure and infections often lowered the blood pressure. Pronounced arterio-sclerosis, in the absence of a raised blood pressure, was usually associated with a poor physical condition. It is suggested that the raised blood pressure of old age is a form of compensation tending to prevent ischemia of vital structures.

Prognosis of Paroxysmal Tachycardia—From the private case records of White and those of the Massachusetts General Hospital Cooke and White collected 750 cases of paroxysmal auricular tachycardia between 1928 and 1938. The likelihood of any particular attack ceasing, in spite of the most alarming symptoms, is practically certain. The death of only 7 patients of the series was due, directly or indirectly, to a paroxysm. When a patient who is seriously ill has an attack the occurrence must be regarded with some apprehension and

heart failure as a result of the attack may lead to the formation of intracardiac thrombi and subsequent emboli. Paroxysmal auricular tachycardia in apparently healthy persons seems to have no effect on the prospect of their longevity. When it occurs late in life its prognosis in general is that of the underlying heart disease. Paroxysmal auricular fibrillation is probably common. When the patient is younger than 40 it may be considered to have no prognostic significance while in later life it may be the first sign of a serious heart disorder. The frequency or the duration of the attacks of paroxysmal auricular tachycardia and fibrillation cannot be foretold.

Recent Trends of Some Infectious Diseases W. J. Martin—p. 540
Reduction of Old Standing Dislocation of Knee Joint F. P. Fitzgerald—p. 542

Treatment of Shock by Action on Nervous Centers—Stern points out that the ordinary methods of combating shock generally do not give positive results because they do not influence the condition of the central nervous system. These negative results may be explained by the presence of the hematoencephalic barrier. Medicinal substances introduced into the circulation have no effect on the central nervous system whereas the introduction directly into the cerebrospinal canal particularly into the ventricles, often has a decided effect. To obtain a positive effect the substance should be introduced intrathecally. This applies particularly to substances normally present in the cerebrospinal fluid and the blood, such as potassium, calcium salts and certain hormones. The antagonism between the central and peripheral parts of the vegetative nervous system, as regards their reaction to the same substance, explains the absence of a positive antishock action of medicinal substances when introduced directly into the circulation. Actually if these substances do penetrate the central nervous system particularly the vegetative centers, they may produce an opposite effect and thereby neutralize the immediate action which they have produced on the peripheral vegetative organs. To produce a direct action on the vegetative nervous centers the substance should be administered directly into the cerebrospinal fluid. The given substance should be introduced into the ventricles of the brain, as its introduction into the subdural or subarachnoid space is usually without effect because it passes rapidly from the cerebrospinal fluid into the blood stream and does not come into contact with the nervous centers. In the last phase of traumatic shock there is first a considerable fall in the tone of the sympathetic nervous system and a partial rise in the parasympathetic tone. The most effective way of combating traumatic shock in its

later phase is to raise the tone of the sympathetic centers by direct action of the vegetative centers, potassium phosphate does this simultaneously. By direct action on the nervous centers the ionic potassium causes an excitability of the sympathetic nervous centers, whereas the ionic phosphate, by concentrating the ionized calcium, decreases the tone of the parasympathetic nervous centers. Potassium phosphate as an antishock remedy is indicated in all those cases in which the tone of the sympathetic nervous centers is decreased. Potassium phosphate must never be used in cases in which the excitability of the sympathetic nervous centers is increased, such as sometimes occurs in the first stage of shock. If hemorrhage is present it must be arrested, because the rise in blood pressure from potassium phosphate will definitely increase it. To avoid a repetition of shock after potassium phosphate is given, the actual cause of shock in particular painful stimuli, must be removed. Potassium phosphate is introduced directly into the ventricles by cisternal puncture. The fluid (1 cc of a solution of potassium phosphate in a concentration of $\frac{3}{4}$ gram molecule with a pH of 7.6) must be introduced with a definite pressure and the direction of the needle must be correct. The patient must be in the horizontal position preferably on the left side, with the head lower than the body.

Syncope in Blood Donors—Poles and Boycott state that among the first 10,000 voluntary blood donors, a tenth of the yearly number, 28 per cent fainted. Their investigation as to whether any particular type of donor is likely to faint and whether prophylaxis is feasible reveals that fainting after the removal of blood affects the two sexes and different builds of people equally but is more common among the young. The incidence is raised by increasing the amount of blood withdrawn from 440 to 540 cc but not by increasing the speed of withdrawal, and by bleeding tired and hungry people but not by a moderately hot and humid atmosphere. The effect of fatigue is difficult to assess, as now many donors are working longer hours than they have ever before and it is difficult to decide who is and who is not fit to give blood. It seems, however, that a man who is used to night work can be bled when he gets through without any ill effects, while to bleed an air raid warden after an unaccustomed night up will often cause fainting. Seltzovsky (1940) also considered that hunger and fatigue were the two most important causes of fainting by blood donors. The loss of 440 cc of blood leaves 97 per cent of blood donors apparently unaffected, and if there is any fall in blood pressure it is small. This fall cannot be reduced by a previous rest, as emotional tension prevents the systolic pressure from assuming its usual stable level. The donors who show the biggest drop in blood pressure also show a slowing of the pulse rate. In those who faint at the end of bleeding the onset of symptoms is almost always associated with a fall in blood pressure and pulse rate. An orthostatic fall in blood pressure may be a temporary phenomenon due to blood loss. It is maximal five to ten minutes after the donor gets up and accounts for one type of delayed syncope. The most dangerous type of faint is that which occurs a half to six hours after bleeding when the donor is back at work or out in the street.

A number of these donors have a transient orthostatic hypotension after being bled, and if it is detected subsequent fainting can probably be prevented by additional rest. Prophylactically, 40 Gm of dextrose to donors was without effect on the rate of fainting, but for men from hot workshops the rate was suggestively (though on the numbers observed not quite significantly) reduced by the ingestion of a liter of isotonic solution of sodium chloride some hours before bleeding. By this procedure the general rate was reduced to 1.75 per cent among the last 2,772 donors bled.

Capillary Fragility—The capillary fragility or resistance as determined at the same session by Gothlin's method of positive pressure and the method of Dalldorf and Russell for negative pressure was compared by Bell and his co-workers in 142 apparently healthy second year medical students between 18 and 23. The correlation was low, in some persons a high negative pressure (500 mm of mercury) produced no petechiae, in others the critical pressure was accidentally overshoot so that several petechiae were produced. With the low correlations of 0.29 obtained, it is not possible with any degree of accuracy to predict a negative pressure reading from a given positive pressure reading or vice versa. If the data are treated as a grouped series according to the positive pressure readings (or alternatively the negative pressure readings) the low correlation becomes more apparent. Each of the tests is consistent within itself. The correlation between readings of one test in different areas varied between +0.77 and +0.89. The problem as to which of the two methods is preferable is not brought nearer solution, nor is any light thrown on the relative importance of vitamins C and P in increasing the resistance of the capillary walls.

Vitamin C Nutrition—The occurrence of sore and bleeding gums in naval ratings and trawler crews which was being labeled scurvy or subclinical scurvy without adequate investigation prompted the authorities to investigate the state of vitamin C nutrition in the Royal Navy. The investigation, McNee and Reid *et al.*, was carried out chiefly by assessing the tissue reserves of ascorbic acid. For control a group of men of similar age and social status engaged in war work in a large motor engineering works was used. Also 9 cases of fully developed scurvy in the wards of the Western Infirmary, Glasgow, during the time the naval investigation was in progress were available. The 9 examples of genuine scurvy in adults do not represent any increase due to war conditions. They were collected to aid the work and would ordinarily have been treated in a number of different hospitals. Most of the 392 Royal Naval ratings and the 176 civilian engineers, whose main sources of vitamin C were potatoes and vegetables, required respectively three and four test doses of 700 mg of ascorbic acid for saturation in the vitamin as compared to five test doses in the spring. Six naval ratings showed sore and bleeding gums out of 118 tested, but it was not possible to associate this with vitamin C deficiency. The ratings of the Royal Indian Navy had lower tissue reserves of vitamin C, yet their teeth and gums were perfect. Evidently good oral hygiene is of major importance in maintaining healthy teeth and gums. The capillary resistance test was of no value in assessing the state of vitamin C nutrition. No relation could be established between the number of petechiae induced and the saturation test. The test was positive in only 1 of 5 patients with fully developed scurvy. In healthy adults, who rely almost entirely on potatoes and vegetables for vitamin C, saturation, as a rule, is extremely deficient. If the present standard of diet is maintained, an outbreak of scurvy is not likely. In adults, at least (growing children are not considered), vitamin C is mainly concerned with tissue repair. In health and ordinary circumstances of service and work the maintenance requirements of this vitamin are small but have not yet been determined accurately.

Sulfathiazole Therapy of Gonorrhea—Schnetz points out that the extraordinary variations in the dosage of the sulfonamides required to effect a cure indicate that the mode of action of this therapy is a complex function with distinct variants. The mode of action of the sulfonamides comprises two phases: inhibition of bacterial growth by fixation of the sulfonamide on the bacterium and destruction of the damaged microbes by phagocytosis and bacteriolysis. The fact that with some sulfonamide compounds fresh cases of gonorrhea responded less favorably to treatment than the older cases indicated the involvement of a third factor, namely immunobiologic processes. The dependence of the efficacy on the duration of the gonorrhea, however, is not as striking a factor with the new and more potent preparations. The author describes investigations on the significance of the two main factors, parasite and host, for the success of the chemotherapy of gonorrhea. The sulfathiazole sensitivity of gonococci fluctuates in culture experiment between 1:500 and 1:128,000. Habituation of the gonococci to the chemotherapeutics can be observed *in vivo* and *in vitro*. The gonococidal properties of the human serum have a thermostable and a thermolabile component and seem to be nonspecific and differ individually. Cases of gonorrhea in which chemotherapy fails often show a high serum resistance. The author regards the following as essential factors in successful chemotherapy of gonorrhea: chemosensitivity of the bacteria, the nonspecific gonococidal activity of the serum and the concentration and duration of action of the drug in the body.

Prostigmine in Tinnitus Aurium—Ysander administered prostigmine to 27 patients with tinnitus aurium. In some of his cases impaired hearing was also improved and occasionally this improvement was so pronounced that the patients reported it spontaneously. In order to eliminate the subjective factor as much as possible, the patients were either not told the purpose of the injections or were told that the results might be positive as well as negative. They were urged to watch the effect on the tinnitus, the hearing and the general condition. As a rule patients were given ten injections of 1 cc of prostigmine methylsulfate (1:2,000 solution). The injections were given at intervals of three or four days. This was followed by taking orally 3 tablets of prostigmine bromide daily for several weeks. Some patients reacted favorably after the first few injections. When the effect proved only temporary a new series of injections was given after an interval of one or two months. Most of the patients had previously been treated unsuccessfully by other methods. In the favorably reacting cases the endoauricular sounds were reduced approximately an hour after the injection, and thus improvement persisted longer after successive injections so that after from four to six injections the improvement persisted for the entire interval. Continued oral medication maintained the improvement for a time. The injections produced favorable effects in some and no effect in others. The complete series usually resulted in some improvement. The treatment was completely successful in 2 cases and gave favorable results in 13, irregular results in 10 and none in the remaining 2. The substance probably acts directly on the labyrinth.

Auricular Flutter Precipitated by Ouabain Injection in Previous Digitalized Patients Case R Zubillaga—p 145

Lymphogranuloma Venereum—According to Borjas the most frequent seat of localization in 250 cases of lymphogranuloma venereum was the entire segment formed by the anus, the rectum and the sigmoid flexure. From here the disease progressed to the perineum and the external genitalia. The disease is caused by a filtrable ultravirus the presence of which can be demonstrated by the allergic reaction to Freis antigen. It is a special type of a sclerosing adenolymphocellulitis of the lower segment of the genitourinary tract and of the rectum combined with a sclerosing rectitis. Chronic stenosing rectitis is the most frequent clinical form. It is more grave than the acute lymphogranulomatous rectitis and chronic rectitis without stenosis which are the early and the intermediate stages of the disease. Chronic stenosing rectitis is more frequent in women than in men. It develops along with other venereal infections especially with syphilis. The local symptoms are those of a chronic rectitis, with more or less acute stenosis, local edema, multiple fistulas, abscesses and elephantiasis. Large rectovaginal fistulas are frequent. The general symptoms are those of acute toxemia and stercoremia. Cachexia occurs relatively quickly in untreated cases. The therapy consists of a permanent colostomy. If the latter fails, radical excision of the rectum, as extensive as in cancer, is indicated.

Splenectomy for Sclerous Congestive Splenomegaly—Annes Dias reports that a man aged 36 experienced one hundred and thirty rectal and ten oral hemorrhages in the course of fourteen years. A clinical and roentgenologic diagnosis of splenomegaly and Laënnec cirrhosis was made early in the course of the disease. Roentgen therapy was not tolerated. Four applications caused severe leukopenia. The Wassermann reaction was negative. Calcium, liver and antisyphilitic therapy failed. When seen by the author the patient presented symptoms of cardiac insufficiency and ascites. He was put to bed and given the proper treatment for his heart condition, vitamins B and C in large doses and liver extract. Splenectomy was performed two months later. The liver appeared normal, the removed spleen weighed 1,500 Gm. The patient was well and working two years later.

Examination of Fundus of Eye: Hypertensive Retinopathy S Vaisman—p 626

Peripheral Shock—Urrutia and his collaborators utilized the Lewis and Perry epinephrine test in a group of 350 persons. The method determines the state of contractility of the cutaneous capillaries. Normal contractility of the cutaneous capillaries oscillates between 7 and 8 cm of mercury. The persons observed included normal persons and patients with decompensated heart with infections and in postoperative collapse. The contractility of the cutaneous capillaries was normal in 155 normal persons and in 36 patients with decompensated heart (from 7 to 8 cm of mercury). The contractility was diminished (5 cm of mercury) in patients with infections and in those with postoperative shock. The test gave normal figures for patients subjected to minor operations and not exhibiting postoperative shock. The test is more sensitive than the mea-

surement of the venous pressure in the diagnosis of peripheral collapse. The test is also of value in the diagnosis of peripheral collapse due to failing heart. These observations indicate that peripheral collapse in the course of infection or after operations is caused by changes in the tonus of the cutaneous capillaries.

Surgical Treatment of Angina Pectoris—Of the 4 methods advocated in the surgical treatment of angina pectoris, sympathectomy, thyroidectomy, revascularization of the myocardium and paravertebral alcoholization, Valdivieso and his associates emphasize the last, pointing out that alcoholization or paravertebral block is a simple intervention which does not involve risks and disadvantages of the other methods. They describe their experience with paravertebral alcoholization in the treatment of 6 men aged between 42 and 61. Five of the patients had been treated for syphilis and all of them had received medical treatment for angina, from which they had suffered for from two to five years. Five patients obtained immediate relief; the sixth was free from pain on the third day after alcoholization. The intercostal pain resulting from the intervention may be confused with the anginal pain. Administration of glyceryl trinitrate will aid in differentiating the two since it has no effect on the neuritis. Effects of alcoholization in 2 cases persisted for six months and in 2 others for a year or more, the other 2 cases have been under observation for only one month. The authors review the experiences of other observers and discuss some of the complications that may result such as pneumothorax, pleural effusion, the Bernard-Horner syndrome, medullary accidents and intercostal neuralgia. They conclude that the paravertebral block by alcoholization is the most innocuous method of providing lasting relief to patients with angina pectoris and suggest that the treatment be extended to other types of cardiovascular pain, such as aortalgia.

Subclinical Cardiac Disturbances in Chronic Tonsillitis—Herve and his associates point out that in the study of the pathogenesis of rheumatic heart disease it is evident that the role of the infectious focus, particularly that of the tonsils, is estimated variously by different authors. They studied two groups. One comprised 110 patients sent to them from the otorhinolaryngologic clinic, nearly all less than 20 years of age, whose disorder was diagnosed as chronic tonsillitis. The other group comprised 50 rheumatic patients who had undergone examination of the rhinopharynx by a specialist. Cardiovascular examination in the course of tonsillitis, particularly in the recurrent attacks revealed the existence of subclinical cardiopathy in 128 per cent of the cases. Examination of the rhinopharynx in rheumatic disease disclosed the presence of a tonsillar focus in 66 per cent of the cases. From the analysis of the two groups it appears that a relationship exists between the rheumatic disease and the active tonsillar focus. This is manifested by allergic phenomena or by direct or indirect microbic action. When a patient with tonsillitis has a sedimentation rate of over 50 mm an hour and a leukocytosis of more than 12,000, it is probable that rheumatic disease is developing. Electrocardiographic changes related to the duration and intensity of the rheumatic process appearing in the course of tonsillitis suggest the existence of active rheumatic disease. Tonsillectomy of rheumatic patients should be performed only after signs of activity have subsided. The administration of sulfonamide compounds before and after tonsillectomy appears to be an effective method of preventing reactivation. Tonsillectomy is beneficial

for the patient with cardiac rheumatism provided the condition of the tonsil is considered. Tonsillectomy does not modify the cardiac lesions caused by the rheumatic disease. Benefits obtained in a large percentage, but not in all, are diminution or cessation of rheumatic activity in its cardiac or articular manifestations, reduction or disappearance of cardiac insufficiency and possibly prevention of the development of endocarditis lenta. Some patients obtain no benefit from tonsillectomy, but it is impossible to foretell this.

Acute Neuritis and Neuromyelitis—Freile and Donoso observed that cases of acute myelitis of unknown etiology were comparatively frequent in their service. They describe 5. The first patient, a man aged 56, presented features of an ascending myelitis and died on the third day. Necropsy disclosed a microscopic abscess in the lateral funiculus of the lumbar part of the spinal cord. The presence of this abscess seems to indicate that the myelitis was of pyogenic origin. This, however, could have been due to medullary softening, which is capable of producing the same appearances, and the abscess was aseptic. Since the necropsy revealed no other septic focus the authors think that a neurovirus was the etiologic factor. Necropsy also disclosed signs of an old meningitis probably of syphilitic origin. They point out that chronic or subacute meningitis is a predisposing factor in ascending myelitis. Three patients between 17 and 33 years of age suddenly developed paralysis of the lower extremities with intense thoracic and lumbar pain and loss of control of the vesical and rectal sphincters. One of these patients died. In view of the absence of morbid antecedents it is assumed that a neurovirus played an etiologic role. The fifth patient, a man aged 44 developed ascending myelitis of Landry's type after having received intrathecal treatment. The paralysis persisted for a month at the end of which time voluntary motion of the limbs returned. The frequency with which neuritic and paralytic symptoms appear in connection with intrathecal treatment is estimated variously at 1 in 1000 or 1 in 5,000 cases. In 25,372 cases in which the slow method of treatment was employed, not a single complication resulted, whereas, with the supertensive treatment, one paralytic accident can be expected in every 30 cases. Some observers ascribe these manifestations to the virus of the diseased animal having inflicted the bite, whereas the majority ascribe it to the fixed virus inoculated therapeutically.

Chronic Intoxication with Manganese—Kaffman and Donoso report that a man aged 64, three months before hospitalization, developed symptoms indicative of manganese poisoning. He had worked in a mine warehouse, and there was some probability that he had had contact with manganese. The disorder took an unfavorable course and the patient died. The microscopic pictures of the brain suggested two possible diagnoses: (1) vascular cerebral syphilis of the noninflammatory type as described by Alzheimer and Nissl and (2) chronic intoxication by lead or manganese, the two conditions causing almost the same microscopic changes. On account of the war the activity in the manganese mines has increased greatly and inspection revealed that the incidence of manganese poisoning is comparatively high among the workers. In one mine 15 of a total of 200 workers had become completely incapacitated by manganese poisoning. The men worked without masks in an atmosphere densely charged with manganese dust. In other mines no cases of poisoning were apparent. Nearly all the miners with manganese poisoning presented the typical disturbances in their walk. Next in importance are the psychic symptoms in the form of attacks of excitation, depression, unmotivated laughter and even true demented states.

CORRECTION

Syndrome Characterized by Gynecomastia—In the abstract of this article in the Current Medical Literature on page 152 of THE JOURNAL of January 9 the phrase "increased excretion of estrogenic substance" (appearing in two places) should read "increased excretion of the follicle stimulating hormone", also in the sixth sentence the word "probable" should read "improbable".

Book Notices

Surgery of Modern Warfare Edited by Hamilton Bailey, FRCS, Surgeon Royal Northern Hospital London. Volumes I and II. Compiled by Seventy-Two Contributors. Second edition. Cloth. Price \$20 per set. Pp 490 481 1000 with 919 illustrations. Baltimore: William Wood & Company 1942.

This two volume work, a compilation from some sixty-five hand picked contributors, brings modern war surgery up to date. It represents British surgery at its best and provides information quite different from that ordinarily found in the conventional textbook. Though the work depicts actual wartime surgical practice, it somehow conveys the impression of current experience—timely, new, nascent, living and dynamic in nature, progressive and undergoing rapid development. Unquestionably time, future experience and analyses of results will furnish more final values relative to war surgery, but nothing in the future can rob this work of its present ability to satisfy the reader of today. The book is actually compelling in its interest, so that the reader finds himself thumbing the pages consulting the index, looking up one subject after another, in order to obtain the latest word on methods, procedures, points of view and opinions.

The volumes are beautifully and lavishly illustrated, thereby abbreviating the text through the avoidance of thousands of descriptive words. The illustrations themselves offer a liberal education in modern surgery. If indelibly transposed to "memory's wall," such pictures should result in better surgeons and better surgery, through improving operative technique and clinical judgment.

These two volumes cover all kinds of war wounds resulting from modern warfare. In all there are some nineteen sections and an appendix.

Section I	Wounds	General Considerations
Section II	Wounds	General Operative Considerations
Section III	Wounds	Special Infections
Section IV	Wounds	Special Considerations
Section V	Wounds of Blood Vessels	
Section VI	Wounds of the Head and Neck	
Section VII	Wounds and Injuries of the Spine	
Section VIII	Wounds of the Trunk	
Section IX	Further General Principles	
Section X	Burns and Frost Bite	
Section XI	Peripheral Nerve Injuries and Wounds of Tendons	
Section XII	Methods of Immobilizing the Limbs	
Section XIII	Wounds of Bones and Joints	
Section XIV	Wounds of the Hand and Foot	
Section XV	Amputations	
Section XVI	Otorhinolaryngology in Relation to War Injuries	
Section XVII	Wounds of the Eye and Orbit	
Section XVIII	Surgical Diseases Encountered in Subtropical Countries	
Section XIX	Administration	
Section XX	Appendix	

While all the sections are probably equally good, especial attention might be called to the unusual excellence of certain chapters which should prove a material aid to all surgeons. "Shock and Its Treatment" (chapter V) by Ernest Finch admirably presents present conceptions. This chapter, like many others in the textbook, covers what is definitely known and then under a separate heading discusses the problems which are still controversial in nature. "Skin Grafting in Wounds Involving Skin Loss" (chapter XIX), written by A. H. McIndoe, reveals the great potentialities of skin grafting in relation to reconstructive surgery. Likewise "Wounds of Arteries" (chapter XXIII), by J. R. Learmonth, covers a vast and important field adequately and within a few pages. "Wounds of the Face and Jaws" (chapter XXV), by James B. Macalpine, is excellent. Seldom does one have the opportunity of reading a treatise on the important phases of the treatment and management of wounds of the face, jaws and neck that deals so practically and efficiently with the subject. A series of approved procedures are detailed, described and outlined, with effective drawings which clarify and illustrate the subject.

This book depicts a new world in war medicine and surgery. It seems to give just what the reader wants to know. It will prove of great value to military surgeons throughout the world,

and especially to those in America who are just entering on their military service. Because of its illustrations it should be of special value to those engaged in teaching the surgery of modern warfare. The work is of unique value today and will always remain a valuable asset to any medical library.

Dr. Hamilton Bailey is to be congratulated on his selection of contributors, on the arrangement and presentation of the subject matter, and on the so timely production of so important a work on the surgery of modern warfare.

Human Pathology By Howard T. Karsner, M.D., Professor of Pathology, Western Reserve University, Cleveland, Ohio. Sixth edition. Cloth. Price \$10. Pp 817 with 484 illustrations. Philadelphia: Montreal & London: J. B. Lippincott Company 1942.

The first edition appeared in 1926, a printing of a sixth edition within sixteen years speaks well for the merits of this standard textbook. The new edition is in many respects a new work. It has been extensively revised and large parts have been entirely rewritten. Much new material has been included but there also has been much judicious pruning. The format of the book has been changed; it is less bulky, the pages are larger, and for greater ease of reading it has been printed two columns to the page. More than one hundred new illustrations have been added or substituted for less instructive ones. As examples of noteworthy changes in the text may be cited the discussions of vitamin diseases, edema shock, spirochetal diseases, rickettsial diseases, the viruses, infectious granulomas, neoplastic diseases, the pneumonias, anemias, tumors of the endocrine glands, tumors of bones and synovia, and virus diseases of the central nervous system. The obvious care the author has given to this revision is reflected in the well chosen bibliography at the end of each chapter. Nearly seven hundred new references have been inserted, and many of the older references have been deleted. The greater majority of the references now are to readily available articles in English. Despite the many changes, the distinctive features of Karsner's book have been retained. As in the first edition, the book presents morphologic alterations wrought by disease in relation to their functional significance. The point of view throughout the book is thoroughly modern. The work can be warmly recommended to medical students as a sound guide, the mature practitioner of medicine will find it a good work of reference.

Adventure in Blood Transfusion By Bertram M. Bernhelm, M.D. Cloth. Price \$2.50. Pp 182 with 9 illustrations. New York: Smith & Durrell Inc. 1942.

Never before has the layman shown such personal interest in the subject of blood transfusion. The yearly number of transfusions has steadily mounted in the last twenty-five years. The development of blood banks in this country has involved thousands of nonprofessional donors. At this writing over 1,200,000 persons have given blood or plasma for the armed forces. Developments in this field have received liberal recognition in the newspapers and magazines, some of the feature articles have been models of exposition of medical subjects for the general public. One cannot help being impressed with the specific knowledge possessed by the layman about blood transfusion. Considering this huge backlog of popular interest it is reasonable to suppose that a book on the subject would have a warm reception and serve a useful purpose. The modern blood donor wishes to know more about the four blood groups, about their detection and about the applications of this knowledge to medicine, biology and the law. He wishes information and reassurance relative to the effect on the donor of giving blood. He is also interested in the use of blood transfusion in military medicine because he is being asked to contribute his blood for that purpose. He is unaware of the long and romantic story of blood transfusion, which would make eminently readable material for the person with an interest in history but without medical background.

This book, it is to be regretted, is not such a book. Written by a surgeon who developed a method of artery to vein anastomosis in 1909, it is preoccupied with his personal experiences with a procedure which rapidly waned when sodium citrate was introduced as an anticoagulant a few years later. The layman will not find in it the answer to most of the common questions which he asks. Only twenty-three pages are devoted to a desultory sketch of the two hundred and fifty year history of the

subject. The bulk of the book, one hundred and fifty-two pages, is occupied by a rather uninteresting case by case report of the development of the method of direct transfusion which the author devised and would not have us forget. A chapter on the role of blood transfusion in the first world war takes only nineteen pages but is sufficiently interesting to be the only part of the book which the reader would like to see expanded. The conclusion is a woefully inadequate chapter of nine pages on the tremendous advances made in the last twenty-five years which betrays the fact that the author has long been dissociated from the field.

Although the general tone is not especially modest, here and there curiously frank and damaging admissions are interspersed. The author states in one place that he published a description of the transfusion cannulas three months before he attempted to use them in a transfusion. He also acknowledges that he was not familiar when he performed his first transfusions with the work of his classmate W. L. Moss on the classification of the blood groups and the necessity for performing compatibility tests.

The style in which the book is written is frequently rhetorical and always circumlocutory. The medical reader is occasionally annoyed by the capitalization of such terms as *menstruonatorum* and Bright's disease. It is difficult to understand the reason for including thirty-four references to the medical literature in a book avowedly written for laymen. It is feared that the reader who seeks gratification for his normal curiosity will be sadly confused by the discussion of outmoded techniques and will lay down the book with his questions unanswered.

The Surgery of Pancreatic Tumors. By Alexander Brunschwig, M.D. F.A.C.S. Professor of Surgery, University of Chicago. Illustrated by Gladys McHugh. Cloth. Price \$7.50. Pp. 421 with 123 illustrations. St. Louis: C. V. Mosby Company, 1942.

This monograph is an important milestone in the surgery of the pancreas. The author, whose keen interest in this field is well known, has summarized and brought down to date the pertinent surgical and pathologic literature of pancreatic tumors. This task in itself is an undertaking of some magnitude, a labor which the author has done well.

The surgical problem presented by tumors of the head of the pancreas is particularly the concern of this monograph. The development of knowledge concerning vitamin K, and the significant relationship of this vitamin to cholemic bleeding, has been an important item in lending impetus to the formidable surgery necessitated by tumors of the head of the pancreas.

Any one who essays to deal with the problem presented by pancreatic tumors will do well to give serious study to this effort of Brunschwig. There have been surgical monographs written on the pancreas before. This is the first time, however, that an author has given special consideration to the problem of the surgery of pancreatic tumors in a monograph of this sort. The nature of the surgery required in many such instances truthfully may be described as being heroic. Patients whose pancreatic ducts are not reimplanted into the bowel and for whom partial gastric resection is done as well—such patients surviving the procedure for some time, should constitute interesting subjects for nutritional studies.

Röntgen Treatment of Diseases of the Nervous System. By Cornelius G. Dyke, M.D. F.A.C.R. Associate Professor of Radiology, College of Physicians and Surgeons, Columbia University, New York, and Leo M. Davidoff, M.D. F.A.C.S. Chief, Department of Surgery, Attending Neurological Surgeon, Jewish Hospital of Brooklyn. Cloth. Price \$3.25. Pp. 198 with 35 illustrations. Philadelphia: Lea & Febiger, 1942.

Here is a brief compilation of the results of radiation on brain and spinal cord tumors together with effects on other miscellaneous lesions of the nervous system. Also included is a survey of the literature on previous experiences with radium and x-ray therapy in nervous diseases. Since the progress of radiation therapy is of recent evolution, this book is timely and serves a useful purpose in recalculating present knowledge on this subject. The more somber aspects of brain tumors are partially dispelled but it remains clear that although radiation therapy offers striking and effective amelioration in many cases it cannot be considered a curative agent. The best and most comprehensive chapter deals with pituitary adenomas and is particularly instructive on present day management of these tumors. The book is augmented by a comprehensive bibliography which

should prove an excellent reference source. There are several defects which are immediately obvious. For one thing, the authors are guilty of serious error in indicating x-ray dosage as 'total dose' or summation of the roentgens given to each of several ports. The value of some of the charts is therefore materially altered. True tumor dosage is not accurately reflected by "total dose." In addition, the book lacks fluency, which might easily have been imparted by careful editing.

Starling's Principles of Human Physiology. Edited by C. Lovatt Evans, D.Sc. F.R.C.I. F.R.S. Jodrell Professor of Physiology in University College, London. The Chapters on the Special Senses Revised by R. Hartridge, M.A. M.D. Sc.D. Professor of Physiology at St. Bartholomew's Medical College, London. Eighth edition. Cloth. Price \$10. Pp. 1,247 with 673 illustrations. Philadelphia: Lea & Febiger, 1941.

This edition of Starling's textbook is much improved over the preceding one in that it gives evidence throughout of more care in preparation and selection of material. The rare feat of successfully integrating the results of new investigations with the classic pictures of function has been successfully accomplished without any ruthless iconoclasm. Of course, it is doubtful whether we have a right to expect any one author, or even any small group of authors, to be able to write in one volume a well balanced textbook of physiology and keep up, at the same time, with the mass of new material being published. While the section on the central nervous system, as well as that on special senses, has been revised thoroughly, that devoted to nutrition is entirely inadequate when one considers the importance this has come to assume in modern civilization. Illustrative material throughout is excellent. The subject index is very complete, but a bibliographic index would be helpful. Specific references are pegged with corresponding subject matter, and general references are grouped at the end of chapter or section. The entertaining style characterizing the original edition has been successfully retained and extended in this edition, which the reviewer considers by far the best of the series for the use of students or physicians.

Apéndice crónica. Consideraciones anatómicas clínicas quirúrgicas. Por el Dr. Fernando M. Bustos, profesor adjunto de clínica quirúrgica de la Facultad de medicina de Buenos Aires. Taper. Pp. 130 with 24 illustrations. Buenos Aires: Editorial El Ateneo, 1940.

The author emphasizes the importance of recognizing and treating associated gastrointestinal lesions, particularly those of the colon associated with chronic appendicitis. He attempts to clarify diagnostic confusion existing in this pathologic entity. The relatively high percentage of failures encountered in his series of 535 surgical cases, despite a well planned preoperative and postoperative medical treatment of the associated pathologic condition, is pointed out. The diagnostician, the author stresses, should make every effort to rule out the possibility of genital pathologic change, since the pain of chronic appendicitis is aggravated during the menstrual periods in the majority of cases. On the whole the book offers interesting reading material particularly to the young surgeon.

Recent Advances in Medicine. Clinical Laboratory Therapeutic. By G. I. Beaumont, M.A. D.M. F.R.C.I. Physician to the Middlesex Hospital, London, and F. C. Dodds, M.A. O.D.Sc. M.D. Courtauld Professor of Biochemistry in the University of London. Tenth edition. Cloth. Price \$5.00. Pp. 440 with 45 illustrations. Philadelphia: Blackiston Company, 1941.

Most important additions to this volume include the considerations of the sulfonamides, the vitamin B complex and vitamins E, K and P, new methods of treating diabetes, gastroscopy, the uses of diethylstilbestrol, the uses of electroencephalography and of phenytoin sodium in epilepsy, the employment of heparin, sternal puncture and plasma transfusion. In order to make use of much new material, a section on basal metabolism previously included has been omitted.

The Essentials of Emergency Treatment. Edited by Herbert Thomas. Cloth. Price \$2. Pp. 144. New Haven: Connecticut State Medical Journal, 1942.

This volume includes a series of essays by a number of Connecticut authors dealing with various factors in emergency medical service. The opening chapter describes the organization and function of this service in Connecticut and is followed by a number of chapters on all of the methods of emergency surgery. This condensation will be found of interest to physicians elsewhere who are concerned with these problems.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

INHERITANCE OF ALLERGIC TENDENCIES

To the Editor—Is the disposition to allergic conditions transmitted as a dominant or a recessive characteristic in the mendelian sense? Where can I find literature pertaining to this problem? M D New York

ANSWER—The exact mode of inheritance of allergy has been in dispute for many years. All investigators, however, agree that no single allergic disease is transmitted as such. That which is transmitted is the predisposition to allergic conditions—the tendency to become hypersensitive. The actual appearance of clinical hypersensitivity depends mainly on environmental factors.

Several investigators have conducted extensive studies to determine the genetic basis for allergy. Adkinson concluded that it is inherited as a simple autosomal recessive. Her report, taken from the genetic standpoint, practically eliminates the possibility of a simple dominant. Cooke and Vander Veer, Spain and Cooke, and Bucher and Keeler found that their figures agreed better with a dominant mode of inheritance, although on analysis their findings are in accord with neither the dominant nor the recessive theory. Bray of England has a substantially different report, this is possibly due to the fact that American studies include statistics on large numbers of hay fever sufferers. In England, because of the absence of ragweed pollen, there is far less hay fever. Richards and Balveat believe that allergy is a partial dominant. All these studies show one main thing—allergic inheritance is not a simple mendelian character. Either there are accessory factors or complete dominance is lacking.

Ratner and his associates take a stand opposite to that of most allergists; they assume that allergy is not an inherited character but is due to placental transmission.

It has been noted in almost all studies that allergic individuals with a bilateral positive family history of allergy have a much earlier average age of onset than those with unilateral histories, who in turn have an earlier average age of onset than those with a negative inheritance.

On the basis of these facts, Wiener, Zieve and Fries have postulated a new theory which involves incomplete dominance. They assume that one pair of alleles (which they call genes H and h) determines allergic inheritance. The dominant gene H is for nonallergic individuals, h is the gene for allergy (recessive). Persons with HH have no allergic predisposition and are considered normal. All hh individuals are allergic, and Hh individuals are either allergic or nonallergic. All the Hh individuals, whether they ever develop any form of allergic disease or not, can still transmit the gene h to their offspring. This theory, then, is the only completely adequate explanation thus far advanced which accounts for the large number of allergic persons with negative family histories.

Wiener, Zieve and Fries divide all allergic persons into two groups according to the age of onset, with the dividing line at 10 years of age. Those with the earlier age of onset are the hh individuals. The 18 per cent of the Hh individuals who develop allergic manifestations have the later average age of onset.

Greater attention should be paid in future studies to the variations of age of onset. Females have a later average age of onset than males; each allergic manifestation has a slightly different average age of onset. Hay fever is apt to begin later than asthma, probably because exposure to pollen is intermittent. Thus it would seem that the dividing line between the two groups of allergic individuals should not be set at 10 but should rather assume the form of a sliding scale, varying with individual manifestations and with sex.

SPINAL FLUID CHANGES IN MULTIPLE SCLEROSIS

To the Editor—The textbooks state that in disseminated or multiple sclerosis the spinal fluid yields a positive colloidal gold curve in about 50 per cent of the cases, some also state that the Wassermann reaction of the spinal fluid is negative. I should like to know the incidence of positive Wassermann precipitin or agglutinin tests of the blood for syphilis in multiple sclerosis.

M D Massachusetts

ANSWER—Demonstrable changes in the colloidal gold reaction in multiple sclerosis were shown in nearly 75 per cent of the patients examined according to the investigations by Merritt who based his findings on a personal examination of 100 cases plus 700 more in the literature. He found a first zone curve in about 25 per cent, a mid zone curve in another 22 per cent, and some slight abnormality in the fluid in a further 24 per cent. It is the first zone curve in the cerebrospinal fluid from cases of multiple sclerosis plus the absence of other abnormalities that is so striking in this disease. The cells and amount of protein may be normal and the Wassermann test negative with a strong first zone colloidal gold test. Such a group of findings is not characteristic of any other disease. Positive Wassermann reactions do not occur in either the blood or the cerebrospinal fluid in multiple sclerosis. If the Wassermann test is found positive in an untreated case, one would always expect other changes in the spinal fluid indicative of syphilis to be found also. The only exception would be if a patient had been thoroughly treated and the other tests had become negative, leaving a positive or a weakly positive Wassermann reaction as the last evidence of syphilis. There should be no confusion between a spinal fluid in a case of multiple sclerosis and a fluid from a case of neurosyphilis, for with active neurosyphilis the cells and globulin are almost inevitably affected. There is no reason, moreover, to believe that the Wassermann or other reactions in the blood sometime would be positive in cases of multiple sclerosis. Neurosyphilis, however, with its many manifestations may produce a syndrome similar to that found in multiple sclerosis, thus confusing the differential diagnosis. One should not depend on cerebrospinal fluid findings alone, but the clinical history, neurologic examination and effects of treatment should all be taken into consideration in differentiating between the two diseases.

STERILIZING QUALITIES OF FREE FLOWING STEAM EQUIPMENT

To the Editor—I have a Rochester steam sterilizer in which I should like to sterilize towels and other cloth materials. Since this equipment does not produce steam under pressure but only at the temperature of boiling water I should like to know how much time it would require to sterilize this material if it can be done at all.

R G Wetterstroem MD Olathe Kan

ANSWER—Moist heat at 100 C suffices to kill the vegetative cells of bacteria in a short time, holding at that temperature for 3 to 5 minutes provides an ample margin of safety. Bacterial spores are considerably more resistant. The spore forming pathogenic bacteria to be considered are (1) the anthrax bacillus—spores killed in ten minutes, (2) the gaseous gangrene bacilli—the spores of *Clostridium welchii* are killed in five minutes, those of the other bacilli appear to be somewhat more resistant though precise data are lacking, (3) the tetanus bacillus—the resistance of spores is variable from strain to strain and usually given as fifteen to ninety minutes. Spores of saprophytic bacteria and higher fungi are much more resistant, the survival of such spores (as those of the botulinus bacillus) for twenty-four hours at 100 C is not uncommon. In general, then, sterility is not attained by such treatment.

In the use of equipment such as that mentioned two points are to be noted (1) penetration of cloth and similar materials by free flowing steam is considerably slower than by steam under pressure, packing is of primary importance and the period of sterilization must be regarded as beginning only when the center of packed material reaches the maximum temperature, (2) any statement as to the efficacy of free flowing steam in the destruction of bacteria applies only to normal atmospheric pressures, at an elevation of several thousand feet such treatment will accomplish little more than pasteurization

LARVA MIGRANS OR CREEPING ERUPTION

To the Editor—What is the distribution and approximate number (annual) of larva migrans (creeping eruption) in the United States?

N E Ruhl MD Weatherford Okla

ANSWER—The terms larva migrans and creeping eruption have been used to describe the disease caused by a number of different larvae which penetrate the skin. In the United States the causative organism is usually *Ancylostoma braziliense* and the disease is endemic in the southeastern and southern coastal regions, being of sporadic occurrence elsewhere. The highest incidence of the disease is in Florida varying in different sections of the state.

Kirby Smith reported in 1925 an incidence of 2,500 cases covering a period of fifteen years in his practice in Jacksonville, many of his cases coming from central and western Florida, while in the past ten years 45 has been the average number of cases seen at the Miami City Clinic annually.

Creeping eruption has been encountered much less frequently in the Carolinas, Georgia, Alabama, Texas and Oklahoma than in Florida.

Reporting of the disease is not required by the health authorities, and a comparatively small number of the total of infestations occurring at any one time are seen by physicians, hence there is no true standard by which the annual incidence of the disease in the United States can be estimated.

TREATMENT OF LATE OSSEOUS SYPHILIS

To the Editor—I should like to have an outline of the beginning treatment for tertiary syphilis involving the frontal and parietal bones. The patient is a woman aged 65 in good health otherwise. I do not know whether the condition is acquired or congenital. The eyes react to light and in accommodation. Neurologic signs are negative. The Koimer and Kahn reactions are 4 plus and there is the involvement of the frontal and parietal bones. Should she have any arsenical treatment or be kept on iodides, mercury and bismuth compounds?

M D Kansas

ANSWER—Information as to the treatment of late osseous syphilis may be obtained in chapters 15 and 17 of the "Modern Treatment of Syphilis," by J E Moore (ed 2, Springfield, Ill., Charles C Thomas), in chapter 17 of "Modern Clinical Syphilology," by John H Stokes (ed 2, Philadelphia, W B Saunders Company), and in numerous other textbooks on the treatment of syphilis.

Speaking generally and in view of the patient's age, it would probably be wise to begin treatment with a course of eight to twelve weekly intramuscular injections of bismuth subsalicylate in oil, each 0.2 Gm, these injections to be administered deep into the muscles of the upper outer quadrant of alternate buttocks. Simultaneously the patient may be given 2 Gm of potassium iodide three times daily, this amount of the drug being administered well diluted with water, milk or any other desired flavored substance after meals. There is no indication for the use of mercury in the modern treatment of syphilis.

On completion of the suggested course of treatment, and assuming that the patient's physical condition is normal except for the syphilitic lesion of the cranial bones, mapharsen may be given at weekly intervals, beginning for a patient of this age with a dose of 30 mg administered by intravenous injection and with subsequent doses of 40 to 50 mg each, depending on the body weight. A representative course of mapharsen would be from twelve to sixteen injections. This in turn should be followed by another course of bismuth and potassium iodide, as outlined.

The aim of treatment for a patient of this age is to give enough treatment to heal the lesions and to prevent their recurrence. For this purpose two courses of bismuth and the one of mapharsen recommended should be sufficient. The effect of this treatment on the blood test is a matter of no importance.

Again depending on the patient's general health and an estimate of her life expectancy, it would probably be desired to test the spinal fluid relatively early in this course of treatment and to base any further treatment than the amount suggested on the result.

EXPOSURE TO FUMES FROM HOT NITROGLYCERIN

To the Editor—I am writing for information relative to the toxicity of hot nitroglycerin. I have come in contact with 2 or 3 persons who undoubtedly have suffered rather severe toxicity from inhaling fumes given off by this chemical and I am unable to cope with this as I do not know the contents of the poisonous gas therefore I have no means of ascertaining a rational treatment for such patients. One patient has suffered a spinal cord lesion simulating if not the same as multiple sclerosis. That I may not have erred in my diagnosis I referred this case to the Barnes Hospital Clinic in St Louis and the diagnosis was confirmed as made by me. I shall thank you for any information you may be able to give me.

A J Butner MD, Harrisburg Ill

ANSWER—At low temperatures, such as 50 C, the product of nitroglycerin evaporation is nitroglycerin. At higher temperatures some decomposition may take place with the formation of nitrous oxides along with the nitroglycerin vapors. This mixture of nitrous oxides and nitroglycerin may be expected at such approximate temperature level as 100 C. At much higher temperatures, but still below the explosion temperature, which approximates 250 C, more nitrous oxides are produced and correspondingly a diminution in the proportion of nitroglycerin. Both of these substances are highly toxic although their actions are dissimilar. The action of nitrous gases culminates in massive pulmonary edema. An earlier characteristic effect is the formation of methemoglobin. Less significant actions are related to the nitrites and are shared by nitroglycerin. Nitroglycerin as a liquid form is absorbable through the mucous membranes with readiness. Both nitrous oxides and nitroglycerin are dangerous when inhaled. As little as 2 mg of nitroglycerin may cause severe poisoning. The foremost feature of acute nitroglycerin poisoning is violent headache. In chronic poisoning, blood cell destruction is prominent. The commoner symptoms, in addition to the headache, are visual disturbance, flushed face, tachycardia, nausea, vomiting, lowered blood pressure and excitability even to the point of mania. It is well known that some degree of habituation occurs, which tolerance is quite transitory being lost even over a two day weekend. To avoid this loss nitroglycerin workers are likely to apply some nitroglycerin to their clothing such as a handkerchief. While such procedure may prevent nitroglycerin headache, it will not prevent some other actions of nitroglycerin, such as blood destruction. Also this practice is harmful for the nitroglycerin worker's family and those about them, for example others on street cars, who being unmured may develop headaches from proximity. The occurrence of a chronic condition on the order of a spinal cord lesion, as mentioned in the query, is possible as a result of multiple cord hemorrhages known to occur in nitroglycerin poisoning. While there are chemical antidotes for acute nitroglycerin poisoning, real industrial prevention must center around the control of exposure through the elimination of cutaneous contact and opportunity for vapor inhalation, and alcoholic intake should be rigidly avoided. While the exact temperature is not mentioned in the query, the temperature should be kept as low as is compatible with industrial requirement, since high temperatures increase the dangers involved.

SEBACEOUS CYSTS OF CHIN

To the Editor—A woman has many small sebaceous cysts about her chin incident to acne elsewhere on her face. Is there any means other than mechanical whereby these can be eradicated? I seem to have controlled to a large extent the further development of the lesions but I now appear to be faced with the need of removing these one by one by hand unless there is some effective wholesale method, such as use of the x rays.

Ursula G Mandel MD Los Angeles

ANSWER—This type of case is always difficult to treat. Roentgen therapy seems to be the method of choice. Eight to ten treatments given at weekly intervals, with a dosage of 75 to 80 roentgens, unfiltered should be given. Most cases of this type will respond to this form of treatment.

CARBON DIOXIDE COMBINING POWER OF PLASMA

To the Editor—In Queries and Minor Notes in The Journal Dec 12 1942 the explanation of the decrease in the carbon dioxide combining power of a plasma after eighteen hours in the ice box is assuredly incomplete. For years in my courses in physiology for medical students I have pointed out that the determination of the carbon dioxide combining power of the plasma of blood which has stood for a number of hours even in the ice box may give a false low reading as the result of glycolysis with lactic acid formation. The lactic acid of course interacts with the alkaline buffers of the blood and thus reduces the alkali reserve and hence the carbon dioxide combining power of the plasma. Glycolysis can be prevented by the addition of sodium or ammonium fluoride to the blood. This problem is adequately discussed in Peters and Van Slyke's "Quantitative Clinical Chemistry" (Baltimore: Williams & Wilkins, 1932 and 1935 vol 1, p 129 and vol 2, p 62).

THE ROLE OF SURGERY AND IRRADIATION IN CANCER OF THE BREAST

FRANK E ADAIR, MD
NEW YORK

There is today much confusion on what constitutes the best method of treating cases of operable cancer of the female breast. A review of the literature throws little light on the subject because of the widely divergent points of view expressed. Unfortunately many opinions are given which are not based on pathologic studies and on careful follow-up physical examinations.

High voltage irradiation was introduced into the armamentarium of therapy about 1923 to 1925. Few clinics in America have had sufficient cases treated by the different methods made possible by varying combinations of surgery and high voltage irradiation, especially since the introduction of the so-called divided dose method by Coutard, to have come to a positive conclusion that would be above statistical errors.

In this report I review the operable cases treated by different methods in an effort to see if it is possible to arrive at a conclusion as to which is the best method to be followed.

Any clinical experiment which involves combinations of radical mastectomy, simple mastectomy or local removal of a breast cancer, together with irradiation as a preoperative measure, or a postoperative procedure, interstitial irradiation and so on, offers no small problem. To carry out the clinical experiment it becomes necessary to lay out a program and adhere closely to it. For purposes of the study I determined to

1 Evaluate radiation therapy as the sole agent in the cure of mammary cancer

2 Evaluate radical surgery alone

3 Evaluate the combination of preoperative irradiation together with radical surgery

4 Evaluate the combination of immediate radical surgery and postoperative irradiation

5 Evaluate the combination of simple mastectomy with axillary irradiation

Many combinations of therapies, although they have been carried out, cannot be discussed here, as they are not within the realm of this paper. They will be considered in a later paper.

For purposes of facilitating the work, all the breast cases are classified along the following lines:

I Malignant tumors of the breast

Carcinoma

- 1 Primary operable
- 2 Operable after a local excision
- 3 Primary inoperable
- 4 Recurrent inoperable
- 5 Prophylactic

Sarcoma

II Benign tumors of the breast

III Lesions due to injury

IV Inflammatory diseases of the breast

During the past twenty-two years there have been admitted to the Breast Department of the Memorial Hospital 12,751 patients, 7,419 of whom had malignant lesions and 5,332 benign and inflammatory lesions. Every cancer case is placed in one of the groups shown in table 1, and it may be of interest to consider the relative proportion of the cases in each classification.

Primary Operable—This classification signifies that the surgeon or radiologist still has the opportunity to cure the patient along the standard lines of radical surgery and/or irradiation. It represents that the cancer is confined to the breast and corresponding axilla. No cases involving the lungs, bones or supraclavicular area can be considered operable.

This classification represents the early or fairly early case of breast cancer. As the result in all probability of educational propaganda on the subject of cancer, the relative percentage of the operable group steadily increases. Of the 7,419 cases of cancer 47.6 per cent fell into this group, and these 3,535 cases represent the basis of the present report.

Operable After Local Excision—This group represents those operable conditions in which a local removal of a cancer has been done before the patient has come to our hospital, where a radical mastectomy was then done. Many physicians will perform a local removal of a tumor in their office or in the hospital, when they would shudder to think of being called on to perform a radical mastectomy. My impression is that often the thought of its being cancer never comes to them before or during the operation.

This group of 283 cases represents a class that receive bad treatment. In the first place, the physician doing the operation is not trained in surgery. Second, he cuts too close to what he believes to be a benign tumor, instead of making a wide excision for an unknown tumor which later proves to be cancer. He has handled the tumor roughly and unquestionably leaves many cancer cells residual in the wound at the site of his cl

Part of the expense of the follow up work as well as certain funds for clinical research were furnished by the Katherine Straub Cancer Fund. Read before the Section on Surgery General and Abdominal at the Ninety Third Annual Session of the American Medical Association Atlantic City, N. J. June 12, 1942.

This group of patients, therefore, is malhandled from the beginning. They often later come to the surgeon after the disease has entered the lymph nodes, infiltrates local breast tissue and at times even with a nodule or two of skin involvement.

Of the 283 cases classified as "operable after local excision" there was a five year salvage of only 53 cases,

TABLE 1—Classification of Cases

Classification	Cases	
	Number	Per Cent
Primary operable	3 535	47.6
Operable after local excision	283	3.8
Primary inoperable	1 398	18.8
Recurrent inoperable	1 639	22.0
Prophylactic	630	7.2
Sarcomas	29	0.4
Total	7 410	

representing 20 per cent. Had the patient been properly handled at the beginning, she at least would have had a 51 per cent chance of five year cure.

Primary Inoperable—This classification signifies that the patient has neglected her disease until it has passed the breast and corresponding axilla, that the disease has entered the supraclavicular space, the chest, or that distant metastasis has occurred. This represents a neglected case, a case advanced beyond the stage at which the surgeon or the radiation therapist has an opportunity for cure by their respective or combined methods.

Fortunately our clinic showed that there is a striking decrease in this group. In 1920 29 per cent of our total breast cancer cases were of this group while in 1935 only 12 per cent were primary inoperable cases—a decrease of two and a half times the percentage of hopeless cases. Of the 1,398 cases of this group, radiation therapy has given a five year salvage in 12, which is 0.8 per cent.

Recurrent Inoperable—This group represents patients who have been operated on elsewhere and who came to us for therapy after an irremovable recurrence had been found. As a rule this is a hopeless group. Of the 1,639 cases, 24 have been salvaged by radiation therapy and surgery, producing a 1.4 per cent salvage.

Prophylactic Group—By this is meant that group which has had radical mastectomy before arriving at our clinic, where we give the postoperative therapy. The five year salvage is lower than anticipated, namely 15.5 per cent.

TABLE 2—Number of Primary Operable Cases, 1920-1942

Total primary operable cases (22 years)	3 652
Primary operable cases of last 5 years	1 664
Primary operable cases of first 17 years	1 986
These included	
Indeterminate cases	613
Determinate cases	1 383

There were 3,552 primary operable cases treated by a variety of methods. Table 2 gives the distribution of these cases. During the first seventeen years almost 2,000 operable cases were treated. As the result of various causes (table 3) 613 cases are not available for exact studies. It is interesting to note that only 6 per cent were actually lost to follow-up. In the age group of the cancer patient, obviously a fair number are lost from causes other than cancer, such as heart disease, diabetes, arteriosclerosis or nephritis. For the operable cases in which radiation treatment alone in the early

days was given there was no method of biopsy such as aspiration, which would give an exact diagnosis and still allow irradiation. A formal surgical biopsy would not only have jeopardized the life of the patient but have precluded the delivery of adequate radiation, because the operative scar breaks down under heavy irradiation. This accounts for the 270 cases with no proved pathologic condition which had to be excluded. Today aspiration biopsy would have made it possible to include a large part of these cases. The indeterminate cases totaled 613, leaving 1,383 cases in which the pathologic condition is known, as well as the details of the five year end result.

SURGERY ONLY

Table 5 gives the results of treatment in the four large treatment classifications. Of the 194 cases treated by surgery alone without any radiation, it should be here stated that this group represents a "selected group" as evidenced by the high percentage of five year salvage, the low percentage of axillary involvement, namely 43 (table 6) and the older age level. The "surgery only" group emphasizes that selectivity is clinically proper if the end results show a high degree of success. However, from the point of view of a clinical experiment, "selection" only adds confusion.

When no axillary nodes were involved, 74.2 per cent five year salvage was obtained. This figure is approxi-

TABLE 3—Primary Operable Cases, 1920-1936 Inclusive Listing Determinate Cases and Cases Which Must Be Omitted Statistically

Indeterminate cases total	613
Determinate cases	1,383

mately the same as that obtained in the better surgical clinics where surgery alone is employed. In the cases in which there was axillary involvement the five year salvage was 47.3 per cent which is decidedly higher than the average obtained in the average good surgical clinic. This figure immediately brings the "surgery alone" group under suspicion and emphasizes the point made by inference that any surgeon can select his patients, but what happens to those who are operable with rather bulky axillary disease who were rejected for the operation and sent to the radiation department for cure? Investigation reveals that irradiation failed to cure them. By costly experience we now know that in mammary cancer, if there is much actual bulk to be handled by radiation therapy, it will fail. In the past we sent many operable patients having at least a "chance" of cure by radical surgery to the x-ray department, where they had less opportunity for cure.

It is interesting that a few patients were treated by simple mastectomy with 71.4 per cent of five year survivals. Even 8 patients were treated by a local removal of the cancer, with 87.5 per cent five year survival. However, the number of patients so treated are too few to have statistical significance.

PREOPERATIVE IRRADIATION

Preoperative irradiation followed by the radical amputation has many adherents. On theoretical grounds this method of treatment should be one of great value.

For a period of six years we subjected every patient whose condition was operable to preliminary irradiation routinely without any suggestion of "selectivity." When one compares the results when patients are treated in this way with treatment by immediate radical mastectomy followed by irradiation a month or six weeks later, one finds that the cure rate is higher among those

before their surgery given us better end results than treatment with other methods, it would have been worth the time lost, the added expense the morbidity, poor wound healing and fibrosis of the lung. But our experience was quite the contrary. To our mind this phase of the controversial problem of the value of preoperative irradiation is definitely settled. It was a great dis-

+5 signifies that patient survived five years -5 signifies the patient died under five years. The table shows how every 1 of the 1383 determinate cases was treated.

treated by the latter method. Table 5 shows that 582 patients with operable cancer were subjected to preoperative irradiation followed by radical mastectomy, 236 had no axillary involvement, of whom 163, or 69 per cent, had a five year survival. Of the 337 patients having axillary involvement 119, or 35.3 per cent, had a five year survival, with a 49.1 per cent over all survival of this group so treated.

Had our experience in the treatment of the total 669 patients who received preoperative irradiation

appointment to find that only 35 per cent of the cancers located in the breast proper were sterilized by modern divided dose methods of the x-rays or the radium pack. This 35 per cent is not to be compared with the 77 per cent accomplishment of immediate radical followed by radiation therapy. Disease in the axilla is somewhat less certain of cure by irradiation. In the first place without an operation no one can state with certainty whether the nodes are involved or not. And in the second place, possibly because of the diminished blood supply of

axillary nodes when compared to that of mammary tissue, which has a heavy blood supply, the sterilizing effect on the cancerous tissues is less than in the breast.

Another point of view will help to explain the fact that cases treated by preoperative irradiation followed by surgery do not have as high a cure rate as those treated by immediate surgery and then postoperative irradiation. This is the loss of time necessary for the irradiation to be given. This may take from four to six weeks, then, following the administration of the total dosage, it frequently requires six to eight weeks for the skin to recuperate sufficiently for surgical intervention if heavy preliminary irradiation has been used. Thus there is commonly a loss of three months. In all probability the good done by the preoperative irradiation is more than overcome by the loss of time resultant from delivering the dosage and waiting for the skin damage to repair.

as my group of "surgery only" cases is so highly selected, it may be well to study his cases in comparison with ours in order to establish a method of evaluating irradiation.

A study of table 8 reveals that the five year survival of Harrington having no involvement of the axilla was improved 5 per cent by the addition of irradiation. In his cases in which axillary involvement was present, again 5 per cent was added by irradiation. If we possessed a group of unselected cases treated by surgery alone, which we do not, we could tell how much irradiation adds, but we already know it to be of such great value that it is now too late to start to obtain an unselected group to be treated only by surgery.

Our salvage in the group having axillary involvement, 41.8 per cent, suggests the probability that selection was also used in this group. The improvement cannot be entirely attributed to the addition of irradiation. After

Only cases in which a full five year follow up was possible are included in the +5 (lived 5 years or more) group.

The morbidity from radiation therapy is often overlooked in our consideration, but, when the final chapter of therapy is written the unhappy consequences of this agent should be given their proportionate consideration.

RADICAL MASTECTOMY AND POSTOPERATIVE IRRADIATION

Of the 277 patients treated by immediate radical mastectomy followed by irradiation, 95 had no axillary involvement. Of these 73 survived, giving a 76.8 per cent five year survival. Of the 177 patients having axillary involvement, 74 survived, giving 41.8 per cent five year survival. These figures are of prime significance because, when compared with the results of treatment by the method of preoperative irradiation followed by radical surgery, they point to a higher percentage of salvage, even though (see table 6) this group has the highest proportion of axillary involvement, namely 64 per cent. It shows that the patients who came early enough to have no axillary involvement have approximately 77 per cent salvage. It also demonstrates that, of those having axillary disease present, the added irradiation is of very great value. A study of cases with axillary involvement from grade 3 and 4 cancers reveals that radiation therapy is of great value in tumors of high malignancy.

As Harrington of Mayo Clinic has a large series of cases treated both with and without irradiation and

the first thirteen years of this study the base of operability was materially broadened in order to minimize any selection of cases and conform as nearly as possible to the criterion of operability of the average surgeon. This will undoubtedly change our end result figures in the future. It will probably give worse survival figures than these here reported but in all probability, it will increase our percentage of five year survivals of the total.

The only criterion for effectiveness in therapy is the percentage of the total number salvaged. During the first five years, 1920 to 1924 inclusive, only 8 per cent of our total breast cancer material obtained a five year salvage. Some explanation should be attempted as to why this 375 per cent increase in over all salvage occurred. I would suggest first that the patients are coming to the surgeon earlier in the course of their disease as a result of education on the subject of cancer on the part of women. Second as a result of coming earlier there is less bulk of axillary involvement with greatly increased opportunity for cure. Third, by experience we no longer are referring a patient with only a moderate opportunity for cure by surgery to the x-ray department, where there is less opportunity for cure. Fourth, the cure rate has gone up in those cases in which there is axillary involvement, because irradiation is here of decided value, particularly in groups 3

and 4 (on the malignancy scale) Not only does irradiation have a direct inhibitory effect on the remaining cancer cells, probably more important is the locking-up process of the cancer cells in the added scar and fibrous tissue as a result of irradiation Here oxygenation and multiplication of cells are minimized by the unfavorable environment of the cancer cells

At this point consideration should be given to the amount of irradiation desirable as a postoperative procedure Common sense should be our guide A sufficient amount should be given to control the residual axillary disease and at the same time not enough to produce lymphedema of the arm If there is a moderate amount of axillary involvement we prescribe a total of 1,800 to 2,000 roentgens If there is a large amount of axillary disease, with cancer spread over as far as the costoclavicular ligament, we prescribe 2,000 to 2,250 roentgens Surgeons inadvertently produce lymphedema of the arm by infection locally or by inadequate or imperfect axillary drainage Local cancerous disease will produce this undesirable condition unknown causes contribute to the abnormal amount of fibrosis choking venous and lymphatic return from the arm However, knowing that radiation given in large amounts frequently produces it it may be wise to limit the total amount to a reasonable but effective quantity

IRRADIATION ONLY

Authorities have stated that external irradiation properly given, should be able to control mammary cancer This has not been our experience We have varied the factors of therapy in many ways to effect control, but only with modest success We have at least proved that it is possible by high voltage irradiation to effect five year survivals Of the 182 patients with operable cancer cases with biopsies given irradiation

TABLE 6—Radical Operations

	Percentage of Positive Node Involvement	Percentage of Five Year Cures
Surgery only	4%	63

	Without	70.2%	
Axilla positive	With	29.4%	41.8%
	Without	24.3%	

only 44 (24.2 per cent) survived the five year period This is an entirely unselected group of cases The cure rate by irradiation (24.2 per cent) compares unfavorably with that of surgery or a combination of surgery and irradiation (table 5) Roentgen therapy for the treatment of cancer of the breast is not an efficient method in the first place, because over half the patients with operable cancer have disease both in the breast and in the corresponding axilla the latter being poorly controlled by irradiation, and, second mammary cancer as a rule is a resistant type of cancer

SIMPLE MASTECTOMY

Some surgeons have become discouraged with the end results of treatment by radical mastectomy and as a result are resorting to simple mastectomy with the addition of axillary irradiation

This movement is not confined entirely to the lowly in surgery It seems to me that it is an unfortunate turn

of events because those minded in the aforementioned way are disregarding the advances made step by step in this field for a quantity as yet unknown In the first place patients in the average clinic will have axillary involvement of from 55 to 63 per cent If radiation therapy could be relied on to sterilize the disease in the axilla, there would be a real rational basis for this procedure, but, unfortunately, external irradiation by itself is not sufficiently effective to be compared with the 30 to 40 per cent salvage by well done radical mastectomy in cases in which there is axillary involvement In this series of 1,383 cases of primary operable breast cancer are included 97 cases in which a simple mastectomy was done They represent selected cases in which we thought it reasonable on account of age poor general condition and apparent freedom from disease to do only a simple procedure Fourteen patients were treated with surgery only 10 having five year survivals, 71.4 per cent Fifty-three had preoperative irradiation followed by the simple mastectomy Of these 28 (52.8 per cent) survived the five year period Thirty patients were treated by simple mastectomy followed by irradiation of whom 22 (73.3 per cent) survived the five year period

Of course one cannot judge when there is no available axillary material for microscopic study as to our effectiveness in so treating this group One can state that we were fairly fortunate in our selection of material on which to attempt this procedure

LOCAL EXCISION

The same can be said of our 63 cases treated by local removal only of the cancer In 7 cases treated by surgery only there were 6 (85.2 per cent) five year survivals After preoperative irradiation 27 patients were subjected to only a local removal of the cancer, with 19 (70.4 per cent) surviving five years Twenty-nine

patients had immediate local removal followed by irradiation of whom 21 (72.4 per cent) survived the five year period

If one were to judge the results of all the cases by the accomplishment of treatment of the 97 simple mastectomies and the 63 local removals, it would appear that such local procedures would be preferable. But it would be disastrous if we were to take a step backward and do simple mastectomies and local removals of cancers as a routine. Those procedures were abolished with the advent of the present day radical mastectomy. One cannot quarrel with the careful selection of cases when, on account of age, poor general condition or other indications, the surgeon elects to carry out the less formidable procedures, provided his end results justify his choice.

It is up to the protagonists of this procedure to produce a series of cases as good as that produced by the combination of radical surgery and irradiation. We shall await with great anticipation a comprehensive report of a series of cases, statistically acceptable, so treated.

In conclusion, table 9 shows that of 1,383 patients with operable cancer carefully traced, 695 survived the five year period, giving an over all salvage of 51 per cent. This figure includes all those given irradiation alone for whom the salvage was much lower than that of treatment by the combination of surgery and irradiation.

SUMMARY

A study of five year end results in 3,535 cases in which an attempt was made to evaluate surgery alone, preoperative irradiation, postoperative irradiation and irradiation alone in the cure of operable breast cancer revealed that the cases treated by surgery alone represented a highly selected group and do not well represent a cross section of the accomplishments of treatment by this method. Our study shows that the preferable method of treating operable breast cancer is immediate radical mastectomy combined with postoperative irradiation. In this series so treated, of those with no axillary involvement 76.8 per cent obtained a five year survival, of those with axillary involvement, 41.8 per cent had a five year survival. This represents a higher salvage than is usually reported, the explanation is probably to be found in the following:

1. Patients with breast cancer come to the surgeon earlier than previously.

2. A partial selection of operable material takes place, which gives a higher cure rate for the operable cases but a lower cure rate for the total breast cancer material. Since the base of operability was broadened in 1933, the cure rate of operable cases will, in all probability, diminish, nevertheless we anticipate that the over all cure rate for the total material will continue to increase.

3. Modern irradiation by the divided dose method has definitely increased the salvage. The grade 3 and grade 4 cancers involving the axilla represented cases with an especially grave prognosis. Irradiation, carefully applied, has greatly improved the opportunity for cure of the grade 3 and grade 4 cancers, and it is in this group of highly malignant cancers that irradiation is most needed and of most value.

The poorest end results obtained in this study were in those unselected cases given irradiation only, namely 24 per cent.

In 695 of the total 1,383 cases, the five year period was survived, making a salvage of 51 per cent.

ABSTRACT OF DISCUSSION

DR SHIELDS WARREN, Boston. The need for a generally accepted classification for primary cancers of the breast has been well presented. It all too frequently happens that small non palpable lymph nodes contain tumor and that large palpable nodes clinically considered by skilled surgeons to be metastatic are only hyperplastic or the site of extensive infiltration by fat cells. Only when large axillary nodes are fixed can clinical evidence be considered acceptable for establishing the existence of metastases. Needless to say, this inability to make a clinical determination of axillary involvement should not influence the radical operative approach. In the laboratory my associates have been studying the prognostic significance of the extent of lymph node metastasis, that is, whether a patient with two of twenty nodes involved differs significantly in outlook from one with sixteen or all of the twenty involved. While criteria of operability are not in the sphere of the pathologist, it has been my experience that in mucinous carcinoma of the breast there may be extensive ulceration of the skin and a large mass of bulky tumor without metastases having occurred so that successful removal may be carried out. It is ordinarily possible to select the more anaplastic, rapidly growing carcinoma and it is easy for the pathologist, as for the clinician to recognize the totally inoperable acute carcinosis or so called inflammatory carcinoma. With the exception of these two groups of tumors, in my hands at least, attempts at histologic grading of carcinoma of the breast have proved only a disappointment.

DR C. D. HAACLSSEN, New York. At the Presbyterian Hospital in New York, Dr. Stout and I have been much disappointed in irradiation. Not only has it failed to cure cancer of the breast, but we have been unable to show that it actually prolongs life when used for inoperable cases. Thus we have had to fall back on surgery as the sole means of cure and have turned our attention to finding ways of using surgery more efficiently. For this purpose we need a reliable method of classifying breast cancers as curable by operation, for we have evidence to prove that operating in the incurable cases shortens life. In analyzing a series of a thousand cases at the Presbyterian Hospital we have studied some twenty nine different clinical features which seemed to us to be of importance in estimating the true extent of the local disease. In our tabulations we use the punch card method, which we have found exceedingly convenient. We included in our tabulations all cases and did not exclude a so called indeterminate group of cases such as Dr. Adair has done. I cannot believe that such exclusion of a selected group of cases is sound statistical practice. From our tabulations we derived a set of criteria for determining operability which we recommend for your consideration. They are (1) the inflammatory type of breast cancer (2) cases of extensive edema of the breast that is, when the edema involved more than a third of the skin area of the breast, (3) satellite tumor nodules in the skin over the breast (4) edema of the arm, (5) intercostal or parasternal nodules, (6) supra clavicular metastases (7) distant metastases (8) development of breast tumor during pregnancy or lactation (none of our cases were cured in this group) (9) the presence of any two or more of the following signs of locally advanced breast tumor — (a) ulceration of the skin, (b) edema of the skin of limited extent, (c) fixation of the tumor to the chest wall (solid fixation), (d) axillary lymph nodes measuring 2.5 cm. or more in transverse diameter, proved by biopsy to contain metastases if decision as to operability turns on this criterion alone, (e) fixation of enlarged axillary lymph nodes to overlying skin or to deep structures of axilla, again proved by biopsy to contain metastases if decision as to operability turns on this criterion alone. The application of these criteria of inoperability in the Presbyterian Hospital series of 640 radical mastectomies (1915-1934) would have obviated a total of 110 of the operations and would not have decreased the number of patients permanently cured by a single one.

DR WILLIAM CRAWFORD WHITE, New York. Dr. Adair is to be congratulated on his careful study of the Memorial Hospital records for the past twenty-odd years. The five year survival rate in the operative cases compares favorably with those

of other clinics. But I am a little puzzled by the 41 per cent survival rate in the cases of axillary metastases. After studying the charts I think that one factor has been his exclusion of the group of cases in which death occurred without clinical evidence of cancer. I do not think that this group, as a whole, should be excluded without benefit of autopsy. In recent years postoperative roentgen therapy has been used generally. Dr Adair feels that it has been of benefit, and I would like to believe that it is so for the comfort it would give the patient and the surgeon. But in his two tables he has presented practically the same results in cases with surgery alone and in surgery plus roentgen therapy after operation. That likewise has been our experience at the Roosevelt Hospital in a study of five year results. On the contrary, we have definitely been able to prolong the life of some patients comfortably for a short period with roentgen therapy after recurrences have been noted. Dr Adair has had the unusual opportunity of using preoperative roentgen therapy in a large group of cases. It has given him the opportunity that comes to but few to analyze the results in this much debated procedure. He has come to the conclusion that it is not beneficial. We are indeed indebted to him for this valuable contribution. In fact, both surgery and roentgen therapy are often only palliative in the primary operable cases which have been discussed here today. Unknown to us metastases are often outside the operative field in the so called early case. How else to explain the 25 per cent mortality from cancer within five years in the best statistics? All this boils down to the fact that our only hope for improved results rests in cancer education so that the patient may be treated more promptly.

DR E. PAYNE PALMER, Phoenix, Ariz. Most of us who have aided in the educational campaign in cancer feel that we have made some progress during the last quarter of a century as far as the public is concerned, but it is questionable how much progress we are making with the medical profession. Unfortunately we, the medical profession, are an egotistical class as a whole. We don't like to have some one from our town or a neighboring town come in and tell us about cancer, so we pay little attention to them. That is shown by Dr Adair's statistics. I have been working with this problem for almost a half century. We must continue to educate the medical profession through our organizations and go ahead with our education of the public. We must teach the doctor that he must suspect cancer, that cancer of the breast is frequent and that most of the benign tumors should be removed. A specimen should be turned over to the pathologist to examine at the time of removal, and if he feels that the specimen should have a frozen section he should do so. If he feels that it is suggestive of malignancy let him tell you to operate. I prefer to have the pathologist make the diagnosis for me. Then I feel that we are going to give the patient a better chance for a cure. Our method has been in class 1 to do a radical operation and when doing so to go as far as you can with the operation. Then we have those patients irradiated, and we have them irradiated by a man who knows what he is doing and what the dosage should be. In class 2 we give an intensive irradiation forty-eight hours before operation, just short of skin tolerance, and again twenty-four hours before. We then do the radical operation and follow up with irradiation. We have found that our results are better by this method than by doing a radical operation and then irradiating afterward. We feel that it is the proper procedure for these patients. By this method wound healing occurs before irradiation has slowed down the healing process. The other cases, as mentioned here, should be treated radically. If you have a supraclavicular gland, do not class it as a nonoperative case but remove the gland. Such patients are going to die unless you are a radical surgeon and unless you are a radical radiologist. I feel that we should be radical surgically and radiologically.

DR U. V. PORTMAN, Cleveland. It is impossible to expect irradiation by the techniques that we use today to cure cancer of the breast. My idea is that it prolongs life and economic usefulness. Group 1 cases are those without axillary metastases. A woman coming with a tumor in the breast, without palpable nodes and with none of the indications of incurable cancer as

Dr Haagensen pointed out, certainly should have a removal of that tumor and a microscopic examination at once. If the tumor is benign nothing else need be done. If the tumor proves to be malignant, it is up to the surgeon to decide how radical an operation he must do. In my experience the incidence in this type of case has been 25 per cent, with 85 to 90 per cent survival in group 1. There is a certain percentage that do not survive because the tumors have not metastasized to the axilla but elsewhere. Irradiation has been of no benefit in this group of cases. In group 2, which consists of 25 per cent of our cases, the surgical curability runs 45 to 50 per cent. 50 per cent of these patients are not cured. Therefore postoperative irradiation is indicated and the lives of some of these patients have been prolonged but the patients have not been cured by the irradiation or by the surgery. In group 3 which is 30 per cent of our cases by operation alone only 5 per cent survived five years, and that number would have survived if nothing whatever had been done, but in that group of patients all of a life has been prolonged because 15 per cent of them have been well for five years. In group 4, those with distant metastases at the time they came for examination, 20 per cent of our cases surgery could not cure nor could irradiation cure, but even then lives were prolonged with a little less than 10 per cent survival for five years. I have not yet been able to decide that preoperative irradiation is indicated. It is manifest from Dr Adair's statistics and Dr White's remarks that a classification for carcinoma of the breast is necessary, because, for example, in the 30 per cent recurrences in cases without axillary metastases operations in advanced stages of the disease were being performed because there were recurrences in so few only 10 per cent without axillary metastases.

DR FRANK E. ADAIR, New York. The question raised by Dr Haagensen as to the best method of reporting end results is proper to bring out for discussion. It richly deserves consideration by men more competent as statisticians and mathematicians than we who are here assembled today. At present the method of reporting end results differs so widely in the hands of different reporters and institutions that often no scientific comparison is possible. The method used by us at the Memorial Hospital has been adopted by the hospital after many conferences between staff members and statisticians, including statisticians of insurance companies. Our method of reporting leaves no place for guesswork as to what happened in a given case. Some national medical body would do well to make a study of the most scientific method of reporting end results and then see to it that no other method than the one adopted is acceptable to medical editors. I recognize that my figures seem too high—and in the paper explain it as best I can. Of the operable cases of the first thirteen years, Dr Burton Lee headed the breast service and in those days Dr Lee believed that irradiation would accomplish more than it actually proved to do in mammary cancer. Many of our cases that were on the borderline of operability were treated in the x-ray department with loss of life in practically all. Today, unless the case is definitely inoperable, surgery is employed. This broadens the base of operability more in conformity with operators of other clinics and keeps from such refined selectivity, so that the majority of clinics are talking the same statistical language.

The Ordinary Mixed Diet—Calcium constitutes a larger proportion of body weight than does any other of the mineral elements. It is very unevenly distributed in the body, over 99 per cent of the total amount normally being in the skeletal system. It is also very irregularly distributed among the staple articles of food, many of which are extremely poor in calcium while milk contains it in abundance, and green leaves in fairly liberal relation to their total solids or calories. A food supply may appear liberal and varied and yet unless milk and green leaf vegetables are well represented it may be calcium poor. Hence the "ordinary mixed diet" of Americans and Europeans at least among dwellers in cities and towns is probably more often deficient in calcium than in any other chemical element—Sherman, Henry C. *Chemistry of Food and Nutrition*. New York: Macmillan Company, 1941.

ENCEPHALITIS

EASTERN AND WESTERN EQUINE AND ST LOUIS
TYPES AS OBSERVED IN 1941 IN WASHINGTON
ARIZONA NEW MEXICO AND TEXAS

W. McD. HAMMON, M.D., DR.P.H.
SAN FRANCISCO

From studies made on the encephalitides in the United States and Canada during the last decade, the evidence favors setting apart from the many types a group of virus infections which appear to be arthropod borne. These infections have come to be known as western equine and eastern equine encephalomyelitis and St. Louis encephalitis. Now, however, they are recognized to be no longer limited geographically to east and west or in host range to horse and man. Epidemiologically and clinically they are closely related. It would seem reasonable therefore to classify them as members of an increasingly large group of diseases which might well be called arthropod borne virus encephalitides and to consider and study them together.

TABLE 1—Results of Neutralization Tests with Three Vemotropic Viruses on Serums from Patients with a Clinical Diagnosis of Virus Encephalitis, Summer of 1941

	Total Tested	Positive to Eastern Equine	Total Positive to Western Equine	Total Positive to St. Louis	Positive to Western Equine and St. Louis
Yakima Valley Wash	24*	0	15	20	15
Pinal County Ariz	15*	0	6	17	5
Other Arizona areas	7**		2	3	1
Upper Rio Grande Valley	6†		6	3	3
Lower Rio Grande Valley and southern Gulf Coast	6	1	0	1	0
Total	61	1	22	44	24

* One serum taken three days after onset found negative to all viruses; no later specimen obtained.

** Four serums taken eight days or less after onset found negative to all viruses; no later specimen obtained. (Antibody to the St. Louis virus is only occasionally encountered by the eighth day.)

† Two were not tested against the St. Louis virus.

Four serums all taken several weeks after onset were negative to all three viruses.

In this paper the extensive epidemiologic studies made during the summer of 1941 in the relatively isolated Yakima Valley, Washington will be summarized briefly. These studies were of a broad nature, planned in advance and observations begun several weeks before the first case occurred. Investigation of previous epidemics in this area made it possible to predict a recurrence and to outline certain problems for intensive research. In addition observations and investigations made in other areas of the western United States will be reported. These other areas studied include Arizona, New Mexico and Texas. Part of the

results from the Washington¹ and Arizona² investigations have been reported elsewhere in more detail, but those from other states are now presented for the first time.

It is often true that comparative studies of several relatively small outbreaks manifesting different age, sex and occupational characteristics, occurring in areas with certain topographical, agricultural and zoological differences yield information not obtained by the study of a single though large, epidemic. An attempt will be made to interpret some of the differences and similarities noted.

HUMAN CASES

Sufficient data for a diagnosis of a virus encephalitis were available from 69 human patients: 26 from the Yakima Valley, Washington, 18 from Pinal County, Arizona,² 9 from other portions of that state, 7 from northwestern Texas and southeastern New Mexico (upper Rio Grande Valley) and 9 from southern Texas and the lower Rio Grande Valley. The diagnosis was based on a combination of clinical findings, spinal fluid examinations and virus neutralization tests.³ Only those cases are included in which the clinical diagnosis was confirmed by either spinal fluid examination or the neutralization test, both in most cases.

Virus Neutralization Tests.—In table 1 are presented the results of virus neutralization tests on 61 of the 69 patients. Unfortunately, both acute and convalescent serums were available for only 12 of the 25 Arizona cases and for but 9 of the 26 from Yakima. From patients in the latter area the titer of antibodies for the St. Louis virus was shown to increase during the interval between the two bleedings of 3 patients, and in 2 of these it also increased for the western equine virus. In 4 others an increase was demonstrated for the western equine strain only. As has been previously emphasized,⁴ a positive test on a convalescent specimen cannot be attributed with certainty to the current disease unless an earlier specimen has been demonstrated to have no antibody or antibody of a lower titer. Some diagnostic significance has been attached to single positive tests for the equine viruses, since in most instances (but not all⁴) antibodies to these viruses in human beings are found only following a clinically recognized encephalitis.

Most of the Yakima cases must be attributed to the western equine virus for antibodies to the St. Louis virus were found in the serums of many normal persons of this area. In Arizona most cases were caused by the St. Louis virus, for an increase in antibody titer for this virus was most frequently demonstrated. All those tested from the upper Rio Grande Valley neutralized the western equine virus and 3 of 4 tested

Read before the Section on Nervous and Mental Diseases at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1942.

The author received assistance in collection and sending of many of the specimens and for collection of certain of the data from Dr. Stanley R. Benner, health officer, Yakima City County Health Department; Dr. I. D. Dunshee, director, Local Health Administration and Miss Marion Stroud, bacteriologist, Arizona State Health Department; Dr. C. W. Gerber, district health officer, Las Cruces, N. M.; Dr. Grady Deaton, district health officer, San Benito, Texas; and many other local health officers cooperating directors of the state health departments, physicians and veterinarians. Dr. Frederick Bang, National Research Council Fellow, contributed to the clinical and epidemiologic studies in the Yakima Valley.

against the St. Louis virus neutralized it also. The southern Texas cases were chiefly of unknown etiology. Bloods drawn from horses and cows in the last area indicated infection with eastern and western equine and St. Louis viruses. In every area there was evidence of the presence and activity of at least two viruses.

In Texas 1 patient was encountered with antibodies to the eastern equine virus. This was a girl 8 years of age who suffered from a relatively mild clinical encephalitis. Fever, stiffness of the neck and an increased spinal fluid cell count were reported by the physician, Dr. G. R. Daschelle of Brownsville, who saw the child once at an office visit during the early acute stage. About three weeks later following apparent recovery, she was found, on examination by me, to have a unilateral Babinski sign with slight spasticity and overactive tendon reflexes in the same leg. She became ill during an outbreak of encephalomyelitis in horses which was proved to be due to the eastern equine virus by repeated isolation of this virus from the brains of horses.⁵ This epizootic began on the Boca Chica flats at the mouth of the Rio Grande River in the area where this girl lived. Blood from an unvaccinated horse on the same ranch was tested and found to have antibodies to the eastern and the western equine viruses. This is the only case^{5a} of the eastern type infection reported in man except during the 1938 outbreak in Massachusetts.

These blood serum tests, together with tests previously reported from some of these same areas⁶ and others including California,⁷ Colorado⁸ and North Dakota,⁹ reported by others, indicate that mixed epidemics may predominate in the Western states. From the experience in Texas it is seen that all three viruses, and probably another one, may be present in the same area. The presence of another virus is postulated because bloods from a number of cases of clinical encephalitis which occurred at the time of the horse epizootic, and just after, failed to neutralize any of the three viruses known to be present. I have been informed that blood from a number of other clinically similar cases from central Texas^{9a} which were examined in another laboratory also failed to neutralize these three viruses. Blood from both of these Texas groups was taken late enough to rule out St. Louis virus infection.

In table 2 it will be noted that the proportion of normal persons in the Yakima Valley with antibodies to the St. Louis virus increases with the length of residence in the valley. This was not a function of age. Similar findings were reported in 1940.¹⁰ None of the

52 normal persons tested had antibodies to the western equine virus, although in the group tested the previous year five such were found in a group of 75 (6⅔ per cent).¹¹ Undiagnosed infections occur therefore, with both viruses. In these instances the central nervous system is either not involved or only slightly involved as far as can be determined by history.

Clinical Diagnosis—Symptoms, physical findings and clinical laboratory tests did not vary significantly from those reported previously from these and other areas.¹² At present no specific etiologic diagnosis can be made on the basis of these clinical data alone.

Sex and Age—Table 3 presents data on sex and age from epidemics in six western areas. In Yakima in 1941 the incidence in the two sexes was equal. The previous year 81 per cent of the cases were in males,¹³ the average age of the 26 patients in 1941 was conspicuously less than that of the previous season.¹³ The Arizona patients, though predominantly infected by the St. Louis virus, were 60 per cent children under 12 years of age.² Seventy-eight per cent were males. These are in sharp contrast to the findings in the St. Louis City and County epidemic of 1933,¹⁴ where

TABLE 2—Antibodies to St. Louis Virus in 1941 in Normal Persons Residing in the Yakima Valley by Years of Residence

Years of Residence in Yakima Valley	Antibodies St. Louis Virus		Per Cent Positive
	Negative	Positive	
0-3	10	1	9.1
4-7	5	3	40.0
8-11	4	3	
12-15	0	1	70.0

the mean age was high and the sex distribution equal. The upper Rio Grande Valley cases were restricted almost entirely to the 50 to 70 year age group, while the lower Rio Grande and southern Gulf Coast cases were mostly in children. No significant sex differences were noted in either of these groups. The sex and age distribution for Kern County, Calif. as given by Buss and Howitt,¹⁵ and of the St. Louis City-County outbreak have been included in the table for comparison.

Although mention has frequently been made of the high susceptibility to encephalitis during infancy and early childhood, based largely on animal experiments¹⁶ and the one relatively small Massachusetts outbreak of

the eastern type equine infection, study of these data from some of the many western epidemics of western equine and St. Louis encephalitis (table 3) shows that age and sex incidence vary greatly. This would seem to indicate that environmental factors affecting exposure to the infection play an important role in determining both age and sex distribution. Obviously none of the earlier general statements regarding a characteristic age and sex distribution for any one of these infections are now tenable.

Case Fatality Rates—Case fatality rates for these same western areas are presented for comparison in table 3. Variation in fatality rates may be partly dependent on age incidence, it would appear. In all instances shown in the table in which the sample is of significant size, the higher case fatality rates occurred in outbreaks when the higher age groups were principally affected. This is true regardless of whether the St. Louis or the western equine infection predominated. The data from New Mexico and Texas are too meager and incomplete to render any rate significant.

ENTOMOLOGIC ASPECTS

The following characteristics were found common to all areas studied: (1) annual epizootics of encephalomyelitis in horses, (2) an epidemic of human encephal-

itis, (3) intermittent flooding (in most instances irrigation), (4) high summer temperature, (5) large numbers of mosquitoes and (6) evidence of the presence of both St. Louis and western equine viruses. Although studies made by us did not include California, the central valley areas of this state also fulfil the six conditions noted. However, another important southwestern human epidemic (St. Louis 1933) occurred under slightly different circumstances.¹⁴ This epidemic occurred in a nonirrigated area during a summer of unusual drought. This resulted in unusual localized areas of intense *Culex* mosquito breeding in the stagnant sewerage and drainage ditches.

The Massachusetts human outbreak of 1938 was also of the sporadic type, occurring during a summer in which there were heavy rains in a nonirrigated area.¹⁷ Thus, in all areas, outbreaks of encephalitis which involved man were associated with the presence of large numbers of mosquitoes. It may be concluded that epidemics may be expected in most instances to recur annually in irrigated areas, only occasionally elsewhere.

During the testing of 12,000 mosquitoes and 4,000 other arthropods for the presence of virus, during the Yakima Valley survey in 1941, St. Louis virus and western equine virus were isolated for the first time in naturally infected mosquitoes.¹⁸ The former was found three times and the latter five times in *Culex tarsalis*. Although laboratory experiments showed that several *Aedes* mosquitoes transmit the equine virus (reviews¹⁹), not one was found infected among 4,353 of these which were caught and tested. To date no laboratory transmission tests have been attempted with *C. tarsalis*^{10a} except those now in progress in Texas in our field laboratory. There, Reeves and I have just completed successful preliminary transmissions of the St. Louis virus by the bite of *Culex tarsalis* and several other species of mosquitoes. The epidemiologic evidence tending to incriminate *C. tarsalis* as a vector for both western equine and St. Louis virus has been summarized elsewhere.²⁰ This evidence is based on its geographic distribution, seasonal activity, selective feeding on domestic animals and the isolation of viruses from naturally infected specimens.

Mitamura's claim of the transmission of the St. Louis virus by *Culex pipiens*²¹ has recently been confirmed by Reeves, Hammon and Izumi.²² Moreover, it has been shown that *Aedes lateralis* will transmit both the St. Louis (Reeves and Hammon²³) and the western equine virus (Reeves²⁴).

TABLE 3—Sex, Mean Age, Deaths and Case Fatality Rates of Encephalitis in Man in Six Western Areas

Area and Year	Predominant Type	Total Cases	Males	Females	Mean Age in Years	Deaths	Per Cent Deaths
Yakima 1940	Western equine	38	47	11	46	13	22.4

** Sex and exact age of 3 patients unknown

itis, (3) intermittent flooding (in most instances irrigation), (4) high summer temperature, (5) large numbers of mosquitoes and (6) evidence of the presence of both St. Louis and western equine viruses. Although studies made by us did not include California, the central valley areas of this state also fulfil the six conditions noted. However, another important southwestern human epidemic (St. Louis 1933) occurred under slightly different circumstances.¹⁴ This epidemic occurred in a nonirrigated area during a summer of unusual drought. This resulted in unusual localized areas of intense *Culex* mosquito breeding in the stagnant sewerage and drainage ditches.

The Massachusetts human outbreak of 1938 was also of the sporadic type, occurring during a summer in which there were heavy rains in a nonirrigated area.¹⁷ Thus, in all areas, outbreaks of encephalitis which involved man were associated with the presence of large numbers of mosquitoes. It may be concluded that epidemics may be expected in most instances to recur annually in irrigated areas, only occasionally elsewhere.

During the testing of 12,000 mosquitoes and 4,000 other arthropods for the presence of virus, during the Yakima Valley survey in 1941, St. Louis virus and

western equine virus were isolated for the first time in naturally infected mosquitoes.¹⁸ The former was found three times and the latter five times in *Culex tarsalis*. Although laboratory experiments showed that several *Aedes* mosquitoes transmit the equine virus (reviews¹⁹), not one was found infected among 4,353 of these which were caught and tested. To date no laboratory transmission tests have been attempted with *C. tarsalis*^{10a} except those now in progress in Texas in our field laboratory. There, Reeves and I have just completed successful preliminary transmissions of the St. Louis virus by the bite of *Culex tarsalis* and several other species of mosquitoes. The epidemiologic evidence tending to incriminate *C. tarsalis* as a vector for both western equine and St. Louis virus has been summarized elsewhere.²⁰ This evidence is based on its geographic distribution, seasonal activity, selective feeding on domestic animals and the isolation of viruses from naturally infected specimens.

variabilis²⁷ have been demonstrated to be capable of transmitting western equine and St. Louis virus, respectively, in the laboratory. A reduviid, *Triatoma sanguisuga* was found infected with the western equine virus in Kansas pastures²⁸. Since *Culex tarsalis* overwinters as an adult, it might also serve to carry the virus over from one season to another.

OTHER VERTEBRATE HOSTS

The Yakima Valley of Washington is a fertile, flat, irrigated valley encircled and subdivided by barren sagebrush hills. Several gaps are formed in these ranges of hills to the north and south by the course of the Yakima River and are so constructed that migration of wild mammals into the valley is quite improbable. This makes it unlikely that equine encephalomyelitis was introduced in this way. Wild migratory birds do enter the valley along the course of the river.

Encephalomyelitis in horses was first recognized in the valley in 1938. As is shown in table 4, there have been since 1938 annual equine and human outbreaks. Despite extensive vaccination of horses for the western equine type of infection during 1939, 1940 and 1941, cases occurred at many and scattered points throughout the valley, either distant from or in close proximity to human cases. As may be seen in the table there is no numerical relation between the number of equine and human cases. Vaccination of horses did not appear to reduce the incidence of the disease in man. These facts render it unlikely that either man or horse acquires the disease directly one from the other or through an insect vector infected by biting only these hosts. From these and other data it appears reasonable to postulate the presence of a widespread, inapparent reservoir.

As a part of the program of study during the 1941 outbreak all of the reported cases in horses were visited and the diagnosis confirmed by clinical examination or autopsy. It is likely that most of the disease in horses in the Yakima Valley was western equine encephalomyelitis, since no case was seen in a horse vaccinated by a competent veterinarian and since in our hands both subcutaneous and intranasal inoculation of the St. Louis virus has failed to produce clinical encephalitis in horses²⁹.

Although numerous cases of encephalomyelitis occurred in horses in all the regions studied, no other vertebrate except man was noted to be visibly affected. In the Yakima Valley area approximately one thousand mammals and birds, equally divided between wild and domestic, were bled for serum neutralization tests against western equine and St. Louis viruses. As controls one hundred and thirty serums from an apparently encephalitis free area on Puget Sound were tested. These controls were negative. In the epidemic valley area approximately 50 per cent of the domestic fowl, 25 to 35 per cent of the domestic mammals and wild birds and 8 per cent of the wild mammals had antibodies for both St. Louis and western equine viruses. These antibodies we attribute to previous infection of

a mild or inapparent nature. The detailed results of these studies are published elsewhere³⁰.

Bloods from horses and cows from Texas were found positive to both these viruses and to the eastern type as well.

Previous to these surveys only a few neutralization tests had been reported on the serums of animals exposed to natural infection³¹ except on horse and man. During the same season when these extensive studies were made Howitt obtained somewhat similar results in a study of the serums of domestic animals in California, though she found a lower proportion of reactors to the St. Louis virus³².

The eastern equine virus occasionally produces epizootic disease in certain birds³³. Ten Broeck³⁴ was probably the first to use the neutralization test to determine the presence of infection in birds. He found antibodies to the eastern virus in a flock of fowls associated with an epizootic in horses. Western equine virus has been isolated from a single prairie chicken which was shot during the course of a survey³⁵.

All these viruses have now been shown repeatedly to circulate in the blood of a number of mammals and birds following subcutaneous inoculation³⁶. Evidence³⁷ that a source for arthropod infection may be readily available in the Yakima Valley³⁷ and the California Valley³⁸—this potential reservoir has been shown to be predomi-

TABLE 4—Approximate Number of Cases of Encephalitis in Man and Horses Yakima Valley 1938 to 1941

Year	Man	Horse
1938	4	4
1939	31	500
1940	53	20
1941	26	40

nantly domestic in nature, associated intimately with the farm, small towns and suburban areas. Elsewhere the reservoir might be of an entirely different nature depending on the feeding habits of the vector and the species of vertebrates present in sufficiently large numbers to serve as a satisfactory reservoir.

PROPHYLAXIS AND CONTROL

Vaccines prepared against the eastern and western equine viruses are now available for human use from commercial firms and will probably afford protection to

36a In the recent transmission experiment with both viruses referred to in footnote 19a, *Culex tarsalis* was successfully infected by feeding on to chickens or ducks which though showing no signs of disease had been inoculated (subcutaneously) forty-eight hours previously with a small amount of a very dilute virus suspension. The mosquitoes later transmitted the virus to other fowl. This proves that these two can serve in nature as inapparent reservoirs for mosquito infection.

men as well as to horses³⁸ However, in most outbreaks morbidity and fatality rates have been so low that mass immunization programs are not indicated³⁹ For restricted groups bivalent or monovalent vaccine has a definite place

From the distribution of cases in the areas we have studied and in those reported by others, together with the recently determined distribution of possible reservoirs in two areas, it becomes apparent that in these localities rural, small town and suburban areas offer the greatest exposure risk Persons who can move into the central areas of cities at the time of an epidemic might well do so to reduce risk of infection Individuals should, of course, adopt all the known methods for protection against mosquito bites Communities which are sufficiently interested in protection of the human population will attempt control of mosquito breeding This may be expected to present many difficulties and will require techniques which are not employed in the control of *Anopheles* for malaria Passage and enforcement of zoning regulations excluding domestic fowl and stock from residential areas might effectively reduce the number of infected mosquitoes in many of those areas in which high morbidity rates now prevail

COMMENT AND CONCLUSIONS

1 It is suggested that eastern and western equine and St Louis encephalitis be classed as members of a group to be called the arthropod borne virus encephalitides

2 Outbreaks occurring in 1941 in Washington, Arizona New Mexico and Texas were studied Serum neutralization tests to several viruses were made on 61 patients

3 On the basis of present knowledge an etiologic diagnosis cannot be made on the basis of clinical findings To make a definite etiologic diagnosis it is necessary to make serologic tests on both an early and a late serum specimen, especially in a St Louis infection

4 The proportion of normal persons in the Yakima Valley with antibodies to the St Louis virus increases with length of residence in the valley (0 to 3 years 9.1 per cent, 12 to 20 years 76.9 per cent) Few were found with antibody to the western equine virus

5 Evidence was obtained indicating the presence of three and possibly four encephalitic viruses in Texas, and for the presence of at least two in each of the other areas (two isolated from the Yakima Valley)

6 From Texas is reported the first case of probable eastern equine infection in man occurring outside of the Massachusetts outbreak The diagnosis is based on clinical history, a positive serum neutralization test on a convalescent specimen and the isolation of the virus from horses involved in the same epidemic

7 Epidemiologic comparisons were made between each of the epidemics studied and between these and several other reported outbreaks

8 Age and sex incidence and case fatality rates vary definitely in different areas, regardless of which virus predominates Previous statements regarding "typical" age and sex distribution and fatality rates of epidemics due to each of these viruses must be revised It is concluded that environmental factors of exposure strongly

influence age and sex distribution and in turn the fatality rates, for these appear to be a function of age (increasing with the mean age)

9 Conditions especially favorable to mosquito breeding were present at the time of epidemics in all areas studied In irrigated areas epidemics tended to recur annually, elsewhere sporadically as mosquito breeding conditions became favorable

10 *Culex tarsalis* mosquitoes were found to be hosts of both western equine and St Louis viruses in the Yakima area Since these findings, *C. tarsalis* and several other mosquitoes, including *Culex pipiens*, have been demonstrated to be capable of transmitting the St Louis infection in the laboratory The role of mosquitoes as vectors of this disease now appears to be established

11 Epidemiologic evidence indicates that in the Yakima Valley there is a widespread inapparent reservoir of these viruses Strong evidence toward the incrimination of domestic animals, especially fowl, in this role is afforded by the results of neutralization tests on the serum of a large group of mammals and birds In addition it has been demonstrated that these animals when suffering an inapparent experimental infection have virus present in the peripheral blood

12 Vaccines against the equine viruses are available, practical and probably effective and should be used in selected groups of heavily exposed persons Because of low encephalitis morbidity rates in most areas they are not recommended for mass immunization programs

13 Mosquito bite protection, larva control, residence in central urban areas and animal zoning restrictions in peripheral urban areas should afford protection in many epidemic areas

ABSTRACT OF DISCUSSION

DR CARL T. BROFCK, Princeton N. J. Equine encephalomyelitis, St Louis encephalitis and poliomyelitis have much in common There are three outstanding characters that I should like to discuss briefly (1) These diseases are more prevalent in summer than at other times of the year, (2) there are localized outbreaks in different parts of the country and (3) serologic evidence shows that they have a much wider distribution than the clinical evidence indicates The fact that these diseases are more prevalent in summer suggests transmission by biting insects You have heard evidence for the transmission of the equine disease by mosquitoes This may not be the only method of transmission of this virus for in our laboratory we have been unable to get evidence for transmission by mosquitoes in natural outbreaks in pheasants The epidemiology suggests that the St Louis virus is also insect borne and there is other evidence to support this view, but it is not as good as with the horse virus disease There is no evidence that poliomyelitis is transmitted by biting insects, perhaps because we have such a poor animal for laboratory experiments, but the possibility that this virus can be transmitted in this way has not been definitely ruled out The second point, that there are localized outbreaks of these diseases, suggests that there are reservoir hosts which show no clinical evidence of disease but from which the virus may go to more susceptible animals The evidence is getting stronger all the time that this is the condition with the horse virus, and the work of Hammon and his associates shows that it may be possible with the St Louis virus There is no evidence at present that this is true for poliomyelitis The widespread distribution of neutralizing antibodies to equine encephalomyelitis virus and the St Louis virus found by Hammon and his co-workers in a number of animals and birds and the presence of antibodies to the two viruses in the same serums are most suggestive One thing seems clear, and that is that in future work search must be made for more than one virus in infected individuals or animals It seems possible that clinical

38 Schlesinger R. W. Morgan I. M. and Olitsky P. K. Significance of Neutralizing Antibody in Experimental Equine Encephalomyelitis Its Relation to the Disease in Man J. A. M. A. 119: 618-620 (June 20) 1942

39 Hammon W. McD. Suggestions for the Possible Control of the American Summer Encephalitides Correspondence J. A. M. A. 118: 66-68 (Jan. 23) 1942

disease may be due to the simultaneous infection with two or more viruses, whereas if there is a single virus present a host may often respond only by the production of neutralizing antibodies with no clinical symptoms. There are so many unsolved problems in these diseases caused by neurotropic viruses that much more work must be done before we can be positive about them.

DR E. C. ROSENOW, Rochester, Minn. Despite the excellent and painstaking work which has been done on the virus the problem is still not solved. I am impressed by the fact that not only one but several types of virus were found, judging by neutralization tests even in the same host, by the vast areas covered by the epidemic and by the changes in the clinical and pathologic picture of the disease as it occurred in the center and outskirts of epidemic areas as the epidemic disappeared. By the use of special methods for the bacteriologic study of material obtained in the epidemic (1941) and by inoculation of animals by methods usually employed it has been possible to isolate and demonstrate simultaneously an encephalitic type of streptococcus and encephalitic virus, as now understood, not only in persons and horses ill with encephalomyelitis but in nine other species of animals, birds or fish manifesting symptoms or lesions of encephalitis in dog, hog, sheep, bat, mink, chickens, goose, wild ducks, pheasant and fish. Virus and this same type of streptococcus have also been demonstrated in emulsions and filtrates of emulsions of mosquitoes and flies within the epidemic zone and proved absent remote from the epidemic. The relationship between the streptococcus and virus was not limited to their demonstration side by side in the material obtained from the nervous and other tissues affected and in other material. Encephalitis streptococcus antigen was demonstrated in persons ill with or in contact with encephalitis by the cutaneous reaction following intradermal injection of the euglobulin fraction of the serum of horses that had been immunized with the encephalitis type of streptococcus and with the euglobulin fraction of the serum of horses that had been immunized with equine encephalomyelitis virus (western type) and by the precipitation reaction. Control injections and precipitation reactions proved negative. The serum of persons, horses and other animals developed antibodies for the streptococcus as well as for virus during attacks of this disease. The encephalitis antistreptococcus serum appeared to have curative effects in the treatment of persons ill with encephalitis. The virus has been produced experimentally from the streptococcus far removed from its original source by growing it in an autoclaved medium (chick mash) which does not turn acid from prolonged growth of the streptococcus and in the brain of fish by merely adding the streptococcus to the water in which normal goldfish and rainbow trout were kept.

DR IRVING J. SANDS, Brooklyn. Those of us who have worked with encephalitis cases since 1917 or so have become convinced that we were dealing with processes caused by different agents. We felt that there were many viruses, not one virus, and it was our conviction that the solution to the problem would rest in the hands of epidemiologists, immunologists and bacteriologists. Measles encephalitis, vaccinia and smallpox encephalitis present a different anatomic picture from mumps and German measles encephalitis. They are different even clinically. Certainly the poliomyelitis picture caused by a virus cannot at all compare with the encephalitides mentioned in the other diseases. After an attack of poliomyelitis the child is well and normal, except for the paralysis resulting from the death of a certain number of anterior horn cells. However the child that has had Economo encephalitis remains a cripple for life. Dr Sylvester R. Leahy and I reported a series of cases of Economo encephalitis from the Bellevue Psychiatric Hospital (Mental Disorders in Children Following Epidemic Encephalitis, *THE JOURNAL*, Feb. 5, 1921, p. 373). In the last decade one has not encountered any cases of Economo encephalitis. At least one does not meet postepidemic encephalitic syndromes following encephalitis as we had fifteen years ago which would seem to indicate that there are some neutralizing antibodies or agents that completely enable an individual to recover from the type of encephalitis that we now encounter as compared with those of 1917-'25 and '28. There is another disease which is rather trying and which we have seen in the

contagious disease hospital. That is the Guillain-Barre syndrome, which some of us are beginning to believe may be virus borne.

DR MAX H. WEINBERG, Pittsburgh. It is unfortunate that the author did not dwell at all on the clinical phases. We must impress on ourselves that we are not dealing with one disease. I for one have seen quite a few cases of Economo encephalitis since 1928. Only last Sunday I saw a case in Brooklyn of postencephalitic parkinsonism with hemiparesis, which is no doubt a case of Economo encephalitis as we diagnose it clinically, and it is not over four or five years old. We must remember the clinical as well as the serologic differences between the encephalitis of St. Louis and the old one Economo for instance. A good many of the patients with St. Louis encephalitis, if I am not mistaken, had hemorrhagic nephritis. This was not the case with the Economo encephalitis. We get in Economo disease not so much mental as parkinsonian changes. Another difference is that Economo encephalitis did not occur in the summer. The first attack in the United States came on in the late fall of 1918. That is when the first case showed up in New York City, and all through that winter we had encephalitis. For three years we had Economo encephalitis every winter. There were differences in the type of encephalitis from year to year. The first year it was manifest mainly by lethargy, that is why the Economo form is called lethargic encephalitis. The third year there was a larger percentage of Borna cases. We must bear in mind, therefore, that in order to be able to present a picture we shouldn't bring out one phase and leave the rest out.

DR JOSEPH W. MOUNTAIN, Washington, D. C. I should like to ask Dr. Bang to elaborate on the control measures that he briefly outlined, also to say in his judgment whether or not these control measures are susceptible of being incorporated into routine administrative practices of state and local health departments. I happen to be chief of the State Relations Division in the Public Health Service, and we are constantly being importuned to institute measures both in anticipation of an outbreak of this disease and when the disease is upon us.

DR L. W. LARSON, Bismarck, N. D. We had an opportunity in Bismarck to study 95 cases during 1941 which were hospitalized. The onset of the disease was invariably abrupt. The average patient complained of headache as the predominating symptom, a few complained of nausea but very few had any vomiting. After a variable number of hours a lethargy developed. The physical findings were characterized by an absence of ophthalmic signs and of neurologic findings which is contrary to some of the other types of encephalitis that have been reported in previous years. The severity of the disease varied a great deal. Some of the patients merged from the lethargy into an actual coma. A very few had delirium. Many of the patients with delirium were very young; in fact, I think three of the four were infants. The temperature ranged from 99.6 up to 102 or 103 F. The pulse usually rose in proportion to the temperature. The diagnosis was confusing in some instances because the patients had signs and symptoms that are too often regarded as being influenzal in nature. However the blood findings indicated leukocytosis with mononuclear increase. The diagnosis was usually based on spinal fluid findings of slight increase in pressure and definite increase in the number of white cells which ranged from a minimum of 30 up to 500. Invariably the differential count in the spinal fluid showed a decided preponderance of lymphocytes. There were a few exceptions, however, especially in young children, in which the first spinal tap revealed a fluid with a preponderance of polymorphonuclear leukocytes. However subsequent taps showed that this preponderance of polymorphonuclears had changed over to a preponderance of lymphocytes. The Pandey test for globulin showed a slight globulin increase but not of any great significance. The cultures that were carried on routinely in our laboratories in the two hospitals failed to reveal the presence of any pyogenic types of organisms. Now as to the sequelae in those 95 cases to the best of our knowledge we have no evidence of sequelae at the present time. I trust that we can make a further report of these cases to clear up the question of the sequelae. But it is obviously too early to do that.

Dr. FREDERICK B. BANG, Princeton, N. J. We are all, of course interested in the control of this disease. It seems that the disease has a reservoir. The evidence is good that both St. Louis and western poliomyelitis are transmitted by mosquitoes and particularly by *Culex tarsalis*. Thus there are three ways that we might control the disease. Get rid of the reservoir. That would involve, on the basis of the present evidence, getting rid of domestic fowl, as far as Yakima is concerned. Secondly, we may get rid of *Culex tarsalis*. This mosquito breeds in overflows from irrigation areas. In Yakima the entire economy of the valley depends on irrigation. Thus control of the mosquito is very difficult. I think that much can be done along these lines. Finally we have the human being. We may prevent the disease in man by administration of vaccine. This is possible only for the western equine and the eastern equine so far. This means that in an area where we can expect to see encephalitis, where it has already begun to appear during the summer, it would be a good idea for those who are continuously exposed to mosquitoes to take such a vaccine. However, since we cannot predict where and when an epidemic will occur, we do not believe that widespread vaccination should be undertaken in any group unless there is good reason for it such as a beginning epidemic.

DOES VITAMIN A DEFICIENCY EXIST IN CLINICAL UROLITHIASIS?

A CLINICAL AND PATHOLOGIC STUDY OF
NINETY-EIGHT CASES

HUGH J. JEWETT, M.D.
LOUISE L. SLOAN, Ph.D.
AND
GEORGE H. STRONG, M.D.
BALTIMORE

Although experimental¹ and clinical investigations² have suggested a relationship between vitamin A deficiency and urolithiasis, our observations based on a study of 98 cases have failed to disclose any evidence of such a relationship in the human being. There can be no doubt that a vitamin A free diet may result in a high incidence of urinary calculi in rats, but a certain skepticism with regard to an actual clinical relationship recently has arisen. This skepticism has resulted from (1) the disagreement among different investigators with regard to the reliability of some of the tests of the light sense and the adequacy of the norms which have been used in diagnosing moderate degrees of vitamin A deficiency,³ (2) the lack of improvement in the light sense following administration of vitamin A to certain patients with urinary calculi⁴ and (3) the extensiveness of the

pathologic changes associated with the urinary calculi in laboratory animals which have been deprived of vitamin A.⁵

Our investigation has consisted in a clinical study of 20 patients and a microscopic examination of 78 autopsy cases, with urinary calculi. In the clinical group we have attempted to select more reliable visual tests for vitamin A deficiency and have supplemented these subjective tests with the determinations of the level of vitamin A in the blood.

CLINICAL STUDIES

In obtaining our data, 20 patients with urolithiasis in the Brady Urological Institute⁶ and 40 normal subjects comprising a control group were given the following series of tests:

1 Ophthalmoscopic examination was made of the ocular media and fundus, the visual fields were tested, and the visual acuity with correction was determined in order to exclude patients with conditions other than vitamin A deficiency which might affect the light threshold.

2 The curve of dark adaptation was determined as follows. The patient was first light adapted by having him view for three minutes an illuminated field the brightness of which was 1,100 millilamberts. At the end of this period of light adaptation a series of measurements of the light minimum or achromatic threshold was made at intervals to determine the rate of decrease in the threshold during dark adaptation. These measurements were continued for forty minutes or longer, until there was no further significant decrease in the threshold. The test field subtended a visual angle of 1 degree and was located 15 degrees to the nasal side of the fixation point. This particular region was selected for two reasons. First the anatomic studies of Osterberg⁷ showed that the concentration of rods is greatest in the region of the retina about 15 degrees from the fovea. Secondly, by making tests of the temporal rather than the nasal retina, i.e. by locating the test spot in the nasal field, we avoid testing the area bordering on the normal blind spot, where slight shifts in the direction of fixation of the eye may result in pronounced changes in the threshold.

3 At the completion of this test, when the eye was fully dark adapted, the threshold was measured at the fovea and at eighteen different locations in the nasal and temporal meridian of the visual field.

The instrument used in making the threshold measurements was devised by one of us (L. L. S.) and has been described elsewhere.⁸ A description of the preexposure field has not yet been published. It consists essentially of a sheet of flashed opal glass illuminated from the rear by a bank of twelve daylight fluorescent tubes. The distance of the patient from the illuminated surface is such that the vertical dimension of the oblong screen subtends a visual angle of 53 degrees, the horizontal dimension a visual angle of 62 degrees. A circle at the center of the screen, the diameter of which subtends a visual angle of 8 degrees, is used to maintain fixation approximately at the center of the screen. The patient is allowed to direct his gaze to any point within the limits of the circle. This is less fatiguing than the attempt to maintain perfectly steady fixation in one direction.

RESULTS OF VISUAL TESTS

The average curve of dark adaptation of the 20 patients with urolithiasis and the average curve of the control group of forty normal subjects are shown

Read before the Section on Urology at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1942.

From the James Buchanan Brady Urological Institute, the Wilmer Ophthalmological Institute and the Department of Pathology, Johns Hopkins University School of Medicine and Hospital.

Dr. Hugh W. Josephs gave many helpful criticisms and suggestions. Dr. Richard H. Follis, Jr. reviewed the pathologic material. Dr. Heinz Herrmann determined the values of vitamin A in the blood.

in chart 1. The close agreement in the two curves shows that there is no significant increase in the average threshold of the patients with kidney stones which would be expected if the majority of these patients had even moderate degrees of vitamin A deficiency. A further analysis of the data was made in order to determine

Chart 1—Rate of decrease in threshold during dark adaptation measured at 15 degrees from fixation point in nasal field. Average adaptation curve of (1) patients with urolithiasis and (2) control group.

whether or not any 1 of the patients with stones had dark adaptation curves above the normal range either in the first section, where the thresholds are determined primarily by the cones or in the second section, where they are determined by the rods. The individual values of the final cone thresholds are shown in the two frequency distribution graphs of chart 2, which gives the data for the 20 patients with urolithiasis and for the control group of 40 normal subjects. The frequency distribution of the thresholds is similar for the two groups. None of the patients with kidney stones have thresholds higher than are found in the control group. The final rod thresholds (after thirty-five minutes of dark adaptation) are given in chart 3. These graphs also show similar frequency distributions for the two groups of patients, none of the patients with stones have rod thresholds higher than are found in the normal group.

The measurements of the final thresholds at nineteen different locations throughout the horizontal meridian have been analyzed in similar fashion. Chart 4 shows the average threshold gradient curves for the group of 20 patients with stones and for the 40 subjects of the control group. It is apparent that there are no signifi-

Chart 2—Distribution of individual values of final cone threshold at 15 degrees in nasal field.

Chart 3—Distribution of individual values of final rod threshold at 15 degrees in nasal field.

cant differences in the average threshold gradient curves of the two groups. In order to determine whether or not any of the patients with urolithiasis had thresholds outside the normal range, the average value of the threshold at the nineteen different locations was computed for each patient. These values are shown in chart 5 in the form of frequency distributions for the

two groups. The graphs show that none of the patients with stones have thresholds greater than some of the subjects in the control group. There is moreover no evidence of any significant trend toward higher thresholds in the group of patients with urolithiasis.

LABORATORY STUDIES

Determinations of the concentrations of vitamin A in the blood plasma were made in the 20 cases of urolithiasis and in 33 normal controls.⁹ A comparison between these two groups is made in chart 6, which shows the distribution of the individual values. None of the patients with urinary calculi had less vitamin A in the blood than the normal subjects. One subject in the control group had a rather low value for vitamin A in the blood, but this individual showed no other evidence of vitamin A deficiency. The reason for this subnormal value as yet has not been determined.

Analysis of the calculi in the 20 cases of urolithiasis showed that the calculus in 4 instances was calcium phosphate. In all of these the urine was infected, and in 2 it was alkaline. There were 7 cases in which calcium phosphate was mixed with oxalate. In 6 of these the urine was sterile and acid, but in 1 the urine was alkaline and contained *Proteus vulgaris*. There were

Chart 4—Final thresholds after complete dark adaptations at nineteen locations in horizontal meridian. Average threshold gradient curves of (1) patients with urolithiasis and (2) control group.

5 cases of almost pure calcium oxalate calculi, in all of which the urine was acid and in 2 instances was infected. In the last 4 cases the stones were not recovered for analysis, and in 1 of these hyperparathyroidism was present.

Certain investigators have reported a number of cases of urolithiasis in which pathologic dark adaptation failed to improve after large doses of vitamin A.¹⁰ In one of these reports¹⁰ it was assumed that the failure to improve was the result of lack of assimilation or utilization of the vitamin. However, the conditions leading to inadequate assimilation or utilization of vitamin A are largely known. If they are found not to be present it has usually been accepted that failure to improve on vitamin A therapy means that the rise in the visual threshold is not due to vitamin A deficiency. Steven and Wald¹¹ in their careful investigation, have confirmed this conclusion and have set up for their criterion for vitamin A deficiency a

9 The estimation of vitamin A in the blood was carried out according to Kimble's method (Kimble M. S. Photocolorimetric Determination of Vitamin A and Carotene in Human Plasma. *J. Lab. & Clin. Med.* 24: 1055-1065 [July] 1939). For the standardization we used crystalline beta-carotene and U. S. P. Reference Cod Liver Oil No. 2 containing 1,700 U. S. P. vitamin A units per gram. The final reading was made in a Klett Summerson photoelectric colorimeter.

decrease in the visual threshold within at least two weeks of regular vitamin A supplementation. These authors assert that a visual threshold above a "normal range" is an inadequate criterion, for high visual thresholds may result from a variety of congenital and acquired abnormalities other than a deficiency in vitamin A. They state that a correlation of the threshold of the dark adapted eye with response to vitamin A

Chart 5—Distribution of individual values of final rod threshold in horizontal meridian. The value given for each individual are the average of measurements at nineteen different locations.

therapy or with the level of vitamin A in the blood has indicated a relatively low incidence of vitamin A deficiency in the general population.

PATHOLOGIC STUDIES

As a check on these clinical and laboratory studies we examined the autopsy material in 78 cases in which urinary calculi were present. Wolbach and Howe¹² have shown that in the albino rat and guinea pig the specific effect of a deficiency of vitamin A is the replacement of the various epithelial lined structures of the body by a stratified squamous keratinizing epithelium and in almost every instance keratinization of the trachea and bronchi preceded that of the urinary tract. Wilson and DuBois¹³ and Blackfan and Wolbach¹⁴ showed that the same changes were encountered in infants dying of vitamin A deficiency, and the latter authors state that the commonest and earliest appearance of the keratinizing metaplasia is in the trachea and bronchi. These and other pathologic changes occurred in laboratory animals when urinary calculi resulted from vitamin A deficiency.

In none of our 78 autopsy cases was there any evidence of metaplasia in the bronchi or bronchioles. Dr. Richard H. Follis, Jr. of the Department of Pathology has summarized the findings in the urinary tract as follows: "There are 3 cases of keratinizing squamous metaplasia, all of which are associated with marked inflammation."¹⁵ This in itself can cause changes histo-

Chart 6—Distribution of individual values of concentration of vitamin A in the blood plasma.

logically indistinguishable from those produced by vitamin A deficiency. There are 3 instances of epithelial proliferation associated with pyelitis cystica or cystitis

cystica which does not resemble the alterations following deprivation of vitamin A.¹⁶ Furthermore it is not conceivable that vitamin A deficiency could be so widespread as is this type of metaplasia which is so frequently encountered in autopsy material. There is 1 case of squamous metaplasia of the ureter associated with inflammation.¹⁷ This is an early change and yet shows none of the other early changes characteristic of vitamin A deficiency."

SUMMARY AND CONCLUSIONS

The rate of dark adaptation and the thresholds of the completely dark adapted eye were determined for 20 patients with urolithiasis and compared with 40 normal subjects. In addition the vitamin A content of the blood in these patients with urolithiasis was determined and compared with that of 33 normal controls.

In 78 autopsy cases with urolithiasis the respiratory and urinary tracts have been examined for the epithelial metaplasia characteristic of vitamin A deficiency.

In none of these 98 cases was there any evidence of vitamin A deficiency.

Although a vitamin A free diet produces widespread epithelial changes which may lead to the formation of urinary calculi in experimental animals as yet there is no positive proof that a "subclinical" vitamin A deficiency is an etiologic factor in urolithiasis in man.

1201 North Calvert Street

ABSTRACTS OF DISCUSSION

DR. DAVID M. DAVIS, Philadelphia: Dr. Jewett and his co-workers have delivered a blow to the rather shaky foundations of the hypothesis that vitamin A deficiency is an important cause of stone formation. That hypothesis rested principally on the finding by other investigators that there was definite vitamin A deficiency in a series of stone cases. However, similar series of other kinds of diseases have also apparently shown vitamin A deficiency, particularly one series of noncalculous urinary tract disease and one series of certain skin diseases. The authors have largely nullified those findings by showing that under careful experimental investigations their series has shown no such vitamin A deficiency. What then, is the relation, if any, of vitamin A deficiency to calculous or noncalculous disease of the urinary tract? One can only say that it still remains to be elucidated. Another member of this section, Dr. Prather, once hypothesized that perhaps in these little animals, particularly rats, the incidence of stone formation might in some way be associated with obstructions caused in these tiny ureters by the proliferation of the epithelium that occurs in vitamin A deficiency. That is certainly a thought which would also tend to explain why it occurs in little animals and not in larger animals such as man.

DR. RUBIN FLOCKS, Iowa City: Following a discussion of the subject with Dr. Jewett I reviewed the material at the University Hospitals and found that there was no evidence of vitamin A deficiency as an associated factor in 100 patients with calcium urolithiasis. This tends to confirm the careful work of Dr. Jewett. He has proved conclusively that in patients with calcium urolithiasis there is no more vitamin A deficiency than in any comparable group of patients with some other disease. However, I wondered whether the problem had been completely cleared up in view of the fact that in most of the patients with stone in the urinary tract the picture that we see at the time we see the patient is an end result. It is not

the picture at the time when the stone is actually forming, and it may well be that, at the time the stone or nucleus started, one of the initiating factors was a vitamin A deficiency. This fits in with some of the experimental work done on animals. It fits in with the known rapid formation of small calculi in acutely ill, bedridden, vitamin deficient individuals. The further growth of these stones, however, has no relation to vitamin A deficiency, as Dr Jewett and his co-workers have conclusively proved. Whether or not vitamin A deficiency is an important associated factor in the formation of the nucleus is, I believe, still a question which can be answered only by providing some means of demonstrating whether or not the patients are vitamin A deficient during the time of the formation of the nucleus. Certainly in light of this work such studies would be worth while.

DR HUGH J JEWETT, Baltimore. With regard to the suggestion of Dr Flocks that perhaps vitamin A deficiency may be present in the beginning, I have this to say. That is purely hypothetical and I think the burden of proof rests on him. These patients with urolithiasis who show a pathologic adaptation when studied with the biophotometer actually may not have a vitamin A deficiency. I can't go into a detailed account of the biophotometer and the criticisms which are found in the literature with regard to it. It is essentially an instrument which fails to give constant results on the same individual day after day. In other words, lack of reproducibility in the results is one of the criticisms. All these patients who are suspected, after biophotometer tests or other tests, of having a vitamin A deficiency should have their blood levels checked for vitamin A.

A MECHANISM OF FATIGUE IN NEURO-PSYCHIATRIC PATIENTS

A PRELIMINARY REPORT

SIDNEY A. PORTIS, M.D.

Associate Professor of Medicine, University of Illinois
College of Medicine

AND

IRVING H. ZITMAN, M.D.

CHICAGO

Fatigue is frequently observed in patients with neuropsychiatric complaints. The mechanism by which fatigue is produced has been little understood by either neuropsychiatrists or others. This preliminary report presents evidence suggesting one of the possible mechanisms and the animal experimentation on which the procedures adopted are based.

Spontaneous hypoglycemia has been noted by many investigators who have attempted to define the variety of settings in which it occurs. Previously Harris,¹ Ross and Josephs² and more recently Wauchope,³ Conn, Wilder and others have reviewed the subject.

Blood sugar levels may fall following interference with many factors in the normal homeostatic mechanism. Liver disease and disease of the pancreas, either from known adenoma or from hyperplasia of the islands of Langerhans, have been cited as the important factors which may cause spontaneous hypoglycemia. Faulty dieting, including errors in intake of carbohydrates and

the lack of assimilable vitamins has also been a known factor. The pituitary-adrenal syndromes of the well known Simmonds' disease and Addison's disease have long been recognized as associated with hypoglycemic manifestations. Recently Renne and Howard⁴ presented a paper on hypoglycemia and tension depression. They studied neuropsychiatric cases and discovered, with their dextrose tolerance test by the oral route the so-called flat curves and found, when these patients were recovering from their tension depressive symptoms, that the oral dextrose tolerance curve returned to near normal.

We were interested in this hypoglycemic state of the disease because of the so-called pernicious inertia which was the most prominent symptom of a patient who was referred to one of us by a neuropsychiatrist and a group of patients who were seen as a part of office consultation. We therefore undertook a study of the underlying metabolic processes, particularly as they affected their dextrose metabolism to see whether we could not in some way determine the factors which produced the hypoglycemia.

EXPERIMENTAL EVIDENCE

Although there are a multiplicity of factors involved in the homeostatic mechanisms which maintain blood sugar levels, we shall discuss mainly those mechanisms associated with the insulin regulatory system.

The exact manner in which the secretion of insulin is controlled is as yet undetermined. Two main theories are propounded to explain this phenomenon—the neurogenic and the humeral. Unfortunately, neither explains all the various manifestations in their entirety. Proof must come from indirect determinations, since the quantity of insulin present in the blood stream is too low to be determined by chemical means or biologic assay.

Neurogenic—That both myelinated and nonmyelinated nerve fibers supply the islands of Langerhans was demonstrated in 1902 by Gentes.⁵ Further it was shown by McCrea⁶ that these fibers are in communication with branches of the right vagus nerve.

Many workers have observed the effects of stimulation of the right vagus on the blood sugar level. Britton⁷ reported a decrease in blood sugar following such stimulation. However, this occurred only when the pancreatic vein was intact but not when it was ligated. An increase in insulin secretion into the pancreaticoduodenal vein was noted after vagal stimulation by Dietrich.⁸

A fundamental contribution was made by Clark⁹ who found that drugs which stimulate the parasympathetic nervous system produce a fall in the blood sugar level of intact rabbits, this effect did not occur following section of the vagus.

The foremost proponents of the vagal stimulation of the island cells have been La Barre and his asso-

ciates. They reported that the normal dextrose level of a dog may be reduced by transfusion of blood from the pancreatic vein of another animal during stimulation of its right vagus nerve.¹⁰

Pursuing this problem further, these same investigators¹¹ seem to have established a relationship to a center in the thalamus which stimulates the pancreatic secretion of insulin when the blood sugar rises. The impulses are transmitted through the vagus tracts to the island tissue. They used 3 dogs with isolated circulatory and nervous systems. In this manner it was discovered that, although removal of the cerebral hemispheres did not prevent the hyperinsulinism resulting from the transfusion of hypoglycemic blood through the isolated head, the separation of the thalamus did abolish this hyperinsulinism. However, Gayet and Guillaume¹² were unable to confirm these results.

Those who support the humoral control believe that the blood sugar level is the predominant factor in insulin secretion. This view is given support by the work of Phillips,¹³ who did not find any effect on sugar tolerance after vagotomy, and by Long and Fry,¹⁴ who claimed that glycogen resynthesis in muscle was not influenced by section of the vagi.

Houssay and his co-workers¹⁵ have shown that the pancreas can produce its own internal secretion after all its extrinsic nerve supply has been removed and that the control of insulin secretion is directly dependent on the blood sugar level. Most workers seem to agree that the blood sugar level is the primary factor but that the neurogenic factor serves in emergencies.

Not much evidence substantiates the claim that the secretion of insulin is dependent on other hormones produced by the endocrine glands whose secretion in turn is controlled by the blood sugar level.

The presence of a "pancreatropic" factor in the pituitary gland is claimed by some while others seem to believe that thyroid extract sensitizes the secretion of insulin.

A more comprehensive view has been taken by Soskin and his collaborators,¹⁶ who believe that the output of insulin is relatively constant and that there is a homeostatic blood sugar regulating mechanism which depends primarily on the liver and which is controlled by the opposing influences of the pituitary, adrenal and pancreatic hormones.

With these experiments in mind and the fact that these psychoneurotic patients studied showed hypoglycemia as one of the important factors of their fatigue we searched for further evidence as to the *modus*

operandi that brought about this hypoglycemic factor in man. Psychiatric and medical literature is voluminous concerning the effect of emotional impulses on the somatic system. It is also well known that continued physiologic activity in any tissue may lead to either hypertrophy or hyperplasia, depending on the type of tissue involved.

Since the pancreas is an end organ and subject to vagal stimulation, we felt that it was logical to assume that the hypoglycemia of psychoneurotic patients was due to a long-continued stimulation of the right vagus nerve. This is based on the hypothesis that emotional processes occur somewhere in the higher integrated cortical centers and that the emotional impulses first go through the hypothalamus and are relayed to the autonomic nervous system, both sympathetic and parasympathetic systems being involved.

Those patients who are depressed would have a more constant stimulation by these emotional factors going through this pathway. It may even be possible that certain emotions influence definite pathways in the nervous system, localizing in the particular organs involved. Therefore this stimulation may lead to increased activity and irritability of the cells of the islands of Langerhans. This may be a temporary or a prolonged manifestation dependent on the degree and duration of the psychic and emotional impulses involved in the mechanism.

In order to establish the validity of this hypothetical conclusion, we studied 4 patients as a preliminary contribution. We first investigated the metabolism of these patients to rule out any other factors which could cause this hypoglycemic state. In none of these patients did clinical evidence of disease explain this manifestation. We then resorted to the intravenous dextrose tolerance test which had been established as a standard in the metabolic laboratories of the Michael Reese Hospital and previously reported by Soskin and his co-workers. We utilized the intravenous method because it gave use more definite scientific criteria as to what happens to the dextrose given to patients in order to study their tolerance. It removed the uncertainty of the variation of absorption which frequently leads to false interpretations when the oral method of dextrose tolerance is used for experimental observations.

Some of these patients showed on $\frac{1}{3}$ Gm of dextrose per kilogram of body weight when given intravenously a flat curve which had been previously interpreted as that seen commonly in hyperinsulinism. In order to substantiate the theory of vagus control in man we repeated the aforementioned experimentation after paralyzing the vagus with hypodermic injections of $\frac{1}{75}$ grain (0.0009 Gm) of atropine and found that the blood sugar curves which were previously flat returned to a near normal. A review of the literature concerning the effect of atropine on blood sugar is variable. Studies have not been conducted in patients or animals under the influence of atropine and with the use of the intravenous dextrose tolerance test. We wish to emphasize this statement because we do not think it is justifiable to draw conclusions from the results of the oral administration of dextrose as affected by drugs. One must always take into consideration the factor of the prolonged and variable absorption of dextrose in the gastrointestinal tract. Therefore we felt it justifiable to conclude that continued vagal stimulation in

the psychoneurotic patient was an important factor in producing functional hyperinsulinism and concomitant hypoglycemia¹⁷

REPORT OF CASES

The following cases are presented to substantiate this evidence

CASE 1—L. M., aged 52, a professional man, complained of extreme fatigue and weakness following a common cold. Long after all signs of infection had subsided the malaise continued, and the patient was unable to carry on his usual professional duties. In his history there had been many periods of prolonged weakness associated with a tendency to perspire profusely. Long vacations were necessary, absenting him from his occupation. Exhaustive physical examination failed to reveal any organic explanation for this symptom complex. The blood pressure was 118 systolic and 76 diastolic. The basal metabolism was minus 35 per cent. Urine and stool analyses gave negative results. The blood count was within the limits of normal. Liver function tests gave negative results. The intravenous dextrose tolerance test, with $\frac{1}{2}$ Gm of dextrose per kilogram of body weight, gave the following results (chart 1): fasting 92, one-half hour after the intravenous administration 92, one hour 76, one and one-half hours 72, two hours 53. This test was repeated three weeks

Chart 1 (case 1)—Intravenous dextrose tolerance test (B) before injection of atropine and (C) approximately thirty minutes after injection of $\frac{1}{2}$ grain of atropine. A, fasting blood sugar levels in both tests; dextrose was then given. D, fatigue; E, no fatigue.

later, after hypodermic injection of $\frac{1}{4}$ grain of atropine sulfate. Sufficient time was allowed for a good therapeutic effect of this drug before a fasting sample was withdrawn and the dextrose again injected intravenously. The following results are recorded: fasting (before atropine) 70, fasting (after atropine) 76, one-half hour after injection of dextrose 123, one hour 93, one and one-half hours 65, two hours 65.

Follow-Up—Since beginning his new regimen of divided feedings plus atropine, described later, he has been able to carry out his occupation well and feels clinically improved.

At present he has submitted himself to a brief psychoanalytic treatment of his complaints, with therapy directed at those psychodynamic manifestations.

CASE 2—Mrs. H. L., aged 46, a housewife, had a syndrome of headaches, epigastric distress and diarrhea, recurrent in nature for the past two years after moderate exertion. There was definite weakness and fatigue following these attacks and

Chart 2 (case 2)—Intravenous dextrose tolerance test (B) before injection of atropine and (C) approximately thirty minutes after injection of $\frac{1}{2}$ grain of atropine. A, fasting blood sugar in both tests; dextrose was then given. D, fatigue; E, no fatigue.

asthma and hunger on moderate exertion. On one occasion, while playing golf, she had a syncopal attack associated with profuse perspiration. Because she had received only transient relief from the psychiatric approach and was bedridden a great part of the time, her psychiatrist asked us to review her case for a possible organic source of her fatigue. She had a history of recurrent migraine which had subsided six years before, after a thorough psychoanalytic treatment. She had had an appendectomy twenty-six years before admission.

Physical examination was essentially negative. Blood pressure was 140/86. There was diffuse tenderness of the left half of the abdomen not associated with any palpable masses.

Intravenous pyelography and complete gastrointestinal studies were negative. Urine and stool analyses were negative. The basal metabolism was plus 61 per cent. Blood chemistry was normal. Blood agglutination tests for organisms of the various dysentery groups were negative, as were fresh and cultured stools for *Endameba histolytica* and other organisms causing diarrhea. The blood count was normal. Liver function was normal.

The intravenous dextrose tolerance test, with $\frac{1}{2}$ Gm per kilogram of body weight, was as follows: fasting 83, one-half hour after intravenous injection of dextrose 67, one hour 71, one and one-half hours 63, two hours 67. The next day in order to see whether we could "shock" the dextrose regulating

Chart 3 (case 3)—Intravenous dextrose tolerance test without atropine. A, fasting blood sugar—fatigue; B, no fatigue; C, moderate fatigue; D, more extreme fatigue.

mechanism with a higher dose, we tried $\frac{3}{4}$ Gm per kilogram, and a typical posthypoglycemic-hypoglycemic curve was produced. The results were as follows: fasting 83, one-half hour after $\frac{3}{4}$ Gm per kilogram 158, one hour 102, one and one-half hours 40, two hours 40.

The first test, e. g., $\frac{1}{2}$ Gm was repeated three weeks later, after injection of $\frac{1}{4}$ grain of atropine sulfate hypodermically. The results were as follows: fasting (before atropine) 89,

fasting (after atropine) 93, $\frac{1}{2}$ Gm per kilogram was given intravenously and then, in one-half hour, the blood sugar was 105, in one hour 92, in one and one-half hours 82 in two hours 71 (chart 2)

The patient has now been on the therapeutic regimen here outlined for two months. She has done remarkably well and is able to engage in her social activities and attend her numerous

Fig. 4 (case 4)—Intravenous dextrose tolerance test (B) before injection of atropine and (C) approximately thirty minutes after injection of $\frac{1}{2}$ grain of atropine. A fasting blood sugar in both tests; dextrose was then given. D fatigue. E no fatigue.

civic organizations. She sleeps eight to ten hours each night without sedation and has a normally functioning gastrointestinal tract.

CASE 3—Mrs. H. S., aged 44, gave a long history of weakness, "shaking sensations," profuse perspiration and protracted diarrhea. These symptoms would come mainly when she was under emotional strain. She quite accidentally discovered that taking sugar would alleviate these symptoms to some extent. Thorough physical, laboratory and roentgenologic examinations failed to reveal any significant findings. The liver function tests were negative. The intravenous dextrose tolerance test with $\frac{1}{2}$ Gm per kilogram of body weight was as follows: fasting 73, one-half hour 93, one hour 76, one and one-half hours 78, two hours 71. We were not able to repeat this test after the injection of atropine but exhibit this case to illustrate the tendency to a "flat type of curve." The patient had to leave the city immediately after the first test because of her work in the American Women's Voluntary Services. We therefore put her on the medical and therapeutic regimen described and she has been on this plan for three weeks. She puts in from ten to twelve hours a day. She does not fatigue. She has no diarrhea. The "shaking sensations" have entirely disappeared and she reported by letter that she has not felt as well in the past fifteen years as she has in the last six weeks (chart 3).

CASE 4—Mr. Y., aged 43, a machinist gave a bizarre history of recurrent attacks of tachycardia and palpitation with associated weakness of the legs. These attacks arose suddenly, would last for a few hours and were accompanied by profuse sweating and faintness. They became so severe that he was unable to continue with his occupation and remained at bed rest a great deal of the time.

He had had an appendectomy three years previously.

Physical examination was essentially negative. The blood pressure was 130/70. There was a moderate tachycardia. The electrocardiogram was normal. Urine and stool analyses were negative. Complete gastrointestinal roentgenograms were negative. A blood count was normal.

One-third Gm of dextrose was injected intravenously with the following results: fasting 80, one-half hour 120, one hour 80, one and one-half hours 60, two hours 56.

Although this was not a typical "flat" curve it did present a good hypoglycemic effect. It is of interest to note that his weakness was improved about one-half hour after the first tolerance test but was definitely worse at the end of two hours.

Following the injection of atropine, the dextrose tolerating curve was as follows: fasting (before atropine) 100, fasting

(after atropine) 95, one-half hour 154, one hour 125, one and one-half hours 118, two hours 114. In this instance there was no associated weakness at the end of the test (chart 4). The patient has been on the therapeutic regimen for four weeks. He has gained somewhat in weight. His tachycardia, palpitation and weakness have almost completely disappeared and he gets a slight recurrence only when he suffers from a severe emotional upset and, since he has been reassured of the lack of serious aspect of this picture, he has reported that he has for the first time a sense of well-being.

Having made these observations, the next step was to develop a therapeutic approach to the problem of continued hypoglycemia. In order that not too readily absorbable carbohydrates in the form of simple sugars be given to the patients the accompanying diet was outlined.

It will be seen that this is essentially a high protein, moderately high fat and relatively high carbohydrate diet but the carbohydrates are in the more complex form and take a more prolonged period for their com-

Outline of Diet

Foods Allowed

Cereals	All cooked and dry macaroni, spaghetti, noodle and rice
Bread	Enriched white, whole wheat, crackers and Melba toast (include daily in diet)
Soup	Vegetable milk soup
Meat	Lean meat and fowl
Fish	Lean fish, shrimp and oysters
Eggs	Two daily, poached and boiled
Cheese	Small portions
Vegetables	All cooked and raw
Fruits	Fresh, stewed and canned
Beverage	Milk, buttermilk, fruit juices, tea, coffee and cream
Dessert	Fruit salad, simple puddings and sponge cake
Butter	Specified amounts

Food to Avoid

Very fat meat or fish, oil, pastry, fried foods and pure sugar. In case of diarrhea omit raw fruit and vegetables, onions, cabbage, corn, dried peas and beans.

Diet Order

Protein	141 Gm
Fat	17 Gm
Carbohydrate	282 Gm
Calories	2714

Menu

Breakfast	Dinner	Supper
Orange juice 4 oz	Cream of vegetable soup 4 oz	Oyster cocktail
Cream 2 oz	Broiled lake trout 4 oz	Broiled steak 3 oz
Oatmeal	oz	Double baked potato
Butter 1 pat	Steamed rice	Fresh broccoli
Bread 2 slices	Tomato salad	Head lettuce
Eggs 2	Lemon and oil dressing 1 teaspoon	Lemon and oil dressing 1 teaspoon
Coffee	Bread 2 slices	Bread 2 slices
	Butter 1 pat	Butter 1 pat
	Fresh apple juice	Fresh fruit cup
	Sponge cake	Tea with lemon
	Milk 8 oz	
	No sugar	
10 a.m.—Milk 8 oz		
3 p.m.—Orange or grapefruit juice (fresh) 6 oz		
8 p.m.—Milk 8 oz		

Note: If the amount is not indicated in ounces or measurement consider average portion.

plete digestion. This was based on twofold evidence: first, that the injection of dextrose in normal dogs at a slow rate greatly increases the tolerance of these animals to subsequent more rapid injection¹⁸ and, second, the deminimization of protein and the formation of carbohydrate goes on at a much slower rate in the liver and therefore the liver will give a more prolonged

secretion of dextrose over a longer period of time and the postdigestive hypoglycemia in these patients will be delayed if necessary to the next intake of food. However, we felt that more frequent feedings than the normal three meals a day was an additional factor of safety to prevent hypoglycemia from becoming manifested in these patients.

In addition, we thought it was clinically indicated from the experimental evidence accumulated that the vagal nerve would be in a state of partial paralysis with the addition of physiologic doses of atropine $\frac{1}{200}$ gram (0.0003 Gm.) three times a day by mouth to the regimen, and finally, in order to assure more complete utilization of dextrose in their muscle metabolism, small doses of thymine hydrochloride were also given three times a day.

RESULTS OF THIS MANAGEMENT

The striking and rapid disappearance of the so-called pernicious inertia made a profound impression on us in the clinical course of these patients. When these patients had been more or less bedridden previously we found that they were able to assume their normal routine type of living quickly. The fatigue disappeared. One patient who had diarrhea, which may be a symptom of hypoglycemia or vagotonia, had normal bowel movements without any other attempt at gastrointestinal control either dietary or medicinal. Although there are too few cases from which to draw any general conclusions, our main reason in reporting the evidence is to stimulate repetition by those who may have an opportunity from their clinical material to study these manifestations in their patients. Furthermore, it may be mentioned incidentally that the psychoneurotic symptoms of these patients were reported to their neuro-psychiatrists as definitely improved.

CONCLUSIONS

1 Fatigue may be a prominent symptom of neuro-psychiatric complaints.

2 There is experimental and clinical evidence to show that a possible mechanism is hyperinsulinism.

3 This hyperinsulinism may be the result of temporary or prolonged stimulation of the right vagus nerve resulting from emotional processes being relayed through the hypothalamus to the autonomic nervous system.

4 The injection of atropine prevents this stimulation and allows the blood sugar curves to return to near normal.

5 Definite clinical improvement has been noted in the few cases thus far studied.

THE FEMALE OBSTRUCTING PROSTATE

ALFRED I. FOLSOM, M.D.

AND

HAROLD A. O'BRIEN, M.D.

DALLAS, TEXAS

John Caulk¹ in 1921 in a paper entitled "Contracture of the Vesical Neck in the Female" as far as we have been able to find is the first to suggest resection for bladder neck obstruction in the female. In that paper only 1 case was reported. In 1935 he again called attention to the subject.

In 1933 Nesbit² reported 2 cases of bladder neck obstruction which he cured by resection.

In 1934 Fite³ reported 1 case in which resection accomplished a brilliant cure.

Caulk in 1937 reported a total of 15 cases coming under this classification. Twelve of these were due

FIG. 1.—Cross section of posterior part of female urethra showing a rich prostatic gland.

to inflammatory contractures, 1 the result of lobulations at the orifice cystoscopically similar to prostatic lobes, 1 the result of a subtrigonal hypertrophy and the other a large papillary mass.

The Dutch urologist Van Houtum,⁴ in an article titled "Prostatism in General and in the Female" reported 2 instances, 1 in a woman aged 41 and 1 in a woman aged 27.

In 1931 Folsom⁵ first emphasized the clinical importance of the group of glands surrounding the posterior

The Stomach of Birds—The Biological Survey division of the Department of Agriculture has been our chief source of authentic information regarding the food of birds. They have examined the stomachs of over 112,000 birds, including practically every species found in this country. They marshal imposing figures not only as to the type but as to the quantity of larvae, worms, insects, scale lice, weed seed and other noxious substances eaten by birds. It is estimated, for instance that in one state (Iowa) the tree sparrows (not English sparrows) alone eat approximately 875 tons of weed seed in one year! Nearly 10 tons every day of summer! They have presented convincing figures of the same sort regarding birds which destroy the boll weevil, the chinch bug and the Japanese beetle.—Menninger, William C. *Bird Study Bull. Menninger Clin.* 6: 94 (May) 1942.

part of the female urethra. He felt then and we feel now that an infection harbored through the years in these glands is probably the cause of the bizarre pathologic picture seen in this portion of the female urethra (figs. 1, 2, 3, 4 and 5).

Fig. 2—Female periurethral prostatic glandular supply.

From our observations of this interesting and important lesion we are convinced that prostatism is a clinical entity that is seen much more frequently in women than is recognized and properly treated. Physicians

Fig. 3—High power view of figure 2 showing prostatic glands with retained secretion.

have so long had their minds closed to the female prostate as nonexistent that they often fail to ask the proper questions to get an accurate and revealing history. Yet, it is our firm conviction that many women who have some type of prostatism are going without proper treatment because physicians have not fully

realized that such conditions do exist and do cause all the clinical symptoms that are seen in similar conditions in men.

Clinically these cases present, in addition to a bladder irritation, some degree of difficulty in voiding. This is varied in our series of cases from simply a sense of obstruction and unfinished business on through varying degrees of obstruction to complete retention. Three out of 15 of our cases have shown this final stage of obstruction, viz. retention. The urine in these cases may show nothing of importance or, on the other hand, be heavily loaded with pus.

In 4 of our cases the bladder urine showed 4+ pus or more, while the urines collected from the right and left kidneys showed no pus and no organisms. In each of these cases the bladder mucosa was not inflamed. Therefore we feel that these cases represent a similar

Fig. 4—High power view of another group of female prostatic glands with retained secretion.

group in the male, in which the pus originates in the posterior part of the urethra from the prostate and seeps back into the bladder through the relatively weak internal vesical sphincter.

A plum cystogram, either in or sodium iodide being used, will frequently reveal a filling defect in the region of the internal orifice similar to the defects seen in men in prostatic hypertrophy (figs. 6, 7 and 8).

On cystoscopic examination one may find a normal bladder wall or a grossly trabeculated wall with cellulitis and even diverticula and calculi. The best observation of the bladder neck in our opinion is made by using both the close vision cystourethroscope and the pan-endoscope. At times we have found the retrograde lens of great value in evaluating a collaret type of enlargement such as seen in figure 11. Not infrequently the bar or collaret may be felt by palpating the urethra through the vagina with the cystoscopic sheath in place.

The majority of the cases that we have seen as well as those reported in the literature show a fibromuscular hypertrophy (fig 9) with fibrous hyperplasia and varying grades of inflammatory reaction. In some cases actual gland structures have been reported, and these seem to be identical with similar lesions in the male.

We have for years considered these cases in the female as an end result of an old chronic prostatitis of varying degrees of severity and showing a variety of type of reaction, and, since we now have ample pathologic evidence that there is a group of glands surrounding the posterior part of the female urethra, which Caldwell⁸ goes so far as to identify as strictly a homologue of the prostate in the male, we may with propriety assume that the two pathologic entities are in fact identical.

Therefore we feel that the most plausible explanation for the pathologic lesion we are discussing is, first, the existence of a homologous group of glands surrounding

In discussing transurethral resection in the female one must readily realize that we have to be much more careful in our technique first, for the simple reason that since we are dealing with miniature prostates we must be more sparing in our bites of tissue removed to insure

Fig 5—Cross section of posterior part of urethra of full term fetus with prostatic gland structures

the posterior part of the female urethra and, second, that these glands do become infected and that after harboring this infection for months or years these bars, collarets and cicatricial contractions are produced.

Dr Hargrove of Baton Rouge, La., supplied figures 10 and 12. This tissue was removed transvesically by a rectoscope loop from a nodular mass filling the posterior part of the urethra in a woman and producing a complete obstruction. We think any one would agree that this is really and truly an adenomatous enlargement of the female prostate. So that while the majority of the cases are inflammatory in character, yet we can and do see frank adenomatous overgrowth.

These lesions lend themselves very readily to transurethral resection. The results are as satisfactory as they are in the male. We should therefore recognize this as a gross clinical entity and begin to offer to these patients the great relief we have for years been affording the male who is similarly affected.

Fig 6—Opaque cystogram in woman with retention. The prostate can be clearly seen as a defect in the lower margin of the bladder shadow. Also cellular diverticula and ureteral regurgitation.

against cutting through the urethrovaginal septum second, for the reason that we do not, as far as we have observed, have a capsule that may be seen during resection and hence act as a guide, third because excessive fulguration may be as bad as too deep a

Fig 7—Opaque cystogram of woman showing filling defect characteristic of small prostatic enlargement.

cut. This accident happened to us in 1 of our cases and on the ninth postoperative day led to the formation of a urethrovaginal fistula which was later repaired. We therefore use as little fulguration as possible, relying on the Foley bag and traction to control the bleeding.

part of the female urethra. He felt then and we feel now that an infection harbored through the years in these glands is probably the cause of the bizarre pathologic picture seen in this portion of the female urethra (figs. 1, 2, 3, 4 and 5).

These lesions lend themselves very readily to transurethral resection. The results are as satisfactory as they are in the male. We should therefore recognize this as a gross clinical entity and begin to offer to these patients the great relief we have for years been affording the male who is similarly affected.

This accident happened to us in 1 of our cases and on the ninth postoperative day led to the formation of a urethrovaginal fistula, which was later repaired. We therefore use as little fulguration as possible, relying on the Foley bag and traction to control the bleeding.

In 5 of our cases the resection was limited to the lower segment of the urethral circumference since we were in these cases dealing with a bar

Fig. 8—Air cystogram in female showing filling defect characteristic of enlarged prostate.

Fig. 9—Section of tissue removed at resection showing the typical fibromuscular hypertrophy with fibrous hyperplasia.

In 9 cases the entire circumference of the urethra was resected. It was necessary to resect the upper segment in 1 of these cases, in which no result was obtained after the first resection which was limited to the lower segment.

Only one death occurred following resection in this series of cases and that of a woman aged 67 with rather severe diabetes who had myocardial damage resulting from a previous coronary occlusion. She had complete retention with blood urea 50.9 mg. She died from cerebral hemorrhage.

After this somewhat cursory discussion of the female obstructing prostate we will report 3 of our cases in some detail leaving the remaining case histories to be published in detail at the end of the paper.

Hattie B., a Negro woman aged 50 came to the outpatient department of Parkland Hospital complaining of having had gradually increasing bladder trouble for the past five years characterized by frequency, burning and difficulty in voiding. This difficulty had grown gradually worse in recent months until she had complete retention of urine. At the time of admission she was unable to void and, when she was catheterized 12 ounces (355 cc) of urine was removed. A plain film

Fig. 10—Section in Dr. Hargrove etc of actual adenomatous hypertrophy of the female prostate gland.

of the kidney, ureter and bladder tract was negative. A cystogram showed a definite filling defect characteristic of mild prostatic hypertrophy (fig. 13). Cystoscopy showed a bladder wall grossly trabeculated with some evidences of a recent acute inflammation. Observation of the bladder neck disclosed a perfectly typical bilateral intraurethral enlargement (fig. 14) with a very acute angle at 12 o'clock and two lateral masses protruding into the lumen of the urethra; these masses were separated from each other at 6 o'clock by a small amount of intervening tissue which did not seem to be hypertrophic.

A transurethral resection was done at which time approximately 12 Gm. of tissue was removed (fig. 15). No unusual difficulties were encountered. A catheter bag was left in place. The patient made a very uneventful convalescence. On the fourth day the catheter was removed. She had complete incontinence for a few weeks and then began to regain control and in three months was entirely continent and has remained so. She feels well and voids her urine normally in every way. She has no retention.

Mrs. H. aged 67 also seen at Parkland Hospital was first seen for bladder irritation and difficulty in voiding which had resulted in retention. The urine was grossly infected.

Cystoscopy showed a collar type of enlargement completely surrounding the internal urethral orifice. The bladder was grossly trabeculated. After preliminary drainage, resection was done. Several bites of tissue were removed from 3 o'clock

through 6 to 9 o'clock. A bag catheter was left in place. Convalescence was very good and on the fifth day the bag was removed. She still was unable to void any urine; the catheter had to be replaced, and during the next three weeks she had fever and there were large amounts of pus in the urine. At intervals the tube was removed in the hope that her inability to void was due to an edema, but at no time could she void.

Fig. 11—Catheter specimen of female bladder opened from above showing internal vesical orifice surrounded by collar type of prostatic enlargement.

Cystoscopy was done again. The resected area was healed nicely, but the remaining upper half of the collar was even more prominent than on previous cystoscopy. Resection was done again at which time the upper half of the collar was removed. When this was done it was found that some more tissue had to be removed at the site of the first resection. At this sitting nearly 6 Gm. of tissue was removed. Her convalescence was satisfactory and after removal of the catheter on the fourth day she could void freely but had a minor degree of incontinence which lasted only a short time. When last seen six weeks after final operation, she was voiding satisfactorily and her general health had improved. She had perfect control and no residual urine.

Mrs. H., a white woman aged 67, had begun to have frequency, burning and difficulty seven years before. This increased gradually until four years later she was unable to void any urine at all. She was seen in one of the large clinics and after careful examination was told that she had paralysis of the nerve of the bladder. This diagnosis was made in spite of the fact that her neurologic findings were normal and her spinal fluid examination was negative. She was told that she would have to learn to catheterize herself and thus empty and wash out her bladder twice daily, for nothing could be done to get her well. She went home and carried out this regimen for the following three years when she began to feel bad in a general way, being nauseated, very weak and having headaches.

At this point we saw her. She gave us the immediate impression of being seriously ill. A plain film of the kidney, ureter and bladder tract showed three stones apparently located in the bladder. Her urine was foul with a terrible odor.

Cystoscopy showed a fiery red bladder over its entire area. It was grossly trabeculated and cellulated and in the dome showed one wide mouthed diverticulum. The three stones could be seen plainly, one part of one being in a cul-de-sac. The ureteral openings could not be identified and no indigocarmine appeared over a period of twenty to thirty minutes. Efforts to catheterize the ureters were made even though they could not be seen but with no success. On observing the internal vesical orifice we could see a very pronounced bar which we thought was

the cause of the obstruction. Excretory urograms showed nothing.

When the patient entered the hospital catheter drainage was instituted and dextrose and saline solution were given intravenously but in spite of these measures she rather rapidly grew worse with the blood urea going from 121 to 178 mg. She died on the fifth hospital day in a typical uremic convulsion.

An autopsy showed massive bilateral hydronephrosis and hydroureter as seen in figure 16. The bladder opened from above showed the stones, trabeculae, the diverticulum and the transverse bar at the internal vesical orifice. Figure 17 shows a larger view of the bladder. The prostatic bar can be seen plainly at the internal urethral orifice.

We feel reasonably sure that if this woman had been recognized as having prostatism when first seen and proper measures had been taken such as a transurethral resection she would have had a good result and her upper urinary tract would have restored itself to a reasonably normal status.

CASE HISTORIES

CASE 1—Mrs. T. V. F., white, aged 42, was complaining of frequency, dysuria, nocturia and slowness of the stream. These symptoms had been present for about ten years and had appeared following radium implantation for the treatment of carcinoma of the cervix. During the five months prior to examination all these symptoms had been definitely increased in severity.

Examination showed the presence of a stricture of the urethra and a chronic granular urethritis with thickening and elevation of the posterior lip of the internal orifice.

Fig. 12—High power view of figure 10.

A transurethral resection of the thickened posterior lip was carried out with a McCarthy resectoscope under sacral anesthesia. A two way catheter was left in the bladder for constant irrigation the first forty eight hours. The postoperative course was entirely uneventful.

Fig. 13—Air cystogram in case II L showing rather pronounced filling defect in region of prostate.

The pathologic diagnosis was muscular hypertrophy of the prostate.

One month after the resection the patient was entirely free from all urinary distress although she still had to get up once at night to void.

Fig. 14—Drawing by Lewis Waters showing bilateral type of enlargement of prostate in case II B. Panoramic view.

CASE 2—Mrs. J. W. S., white, aged 60, complained chiefly of difficulty in passing urine. She first noticed this trouble two years prior to examination and stated that the difficulty in starting her stream was definitely increasing in degree. During the six weeks prior to examination she had had complete retention on two occasions requiring catheterization.

During the two years that her symptoms had been present she had received some relief from dilations of the urethra; however, as soon as these treatments were stopped the difficulty in starting the stream recurred.

Her general physical findings were normal.

Examination of the urethra showed a persisting stricture, so that a number 24 I cystoscope was held rather tightly in spite of the history of frequent urethral dilations during the past two years. There was pronounced thickening of the posterior lip of the urethral orifice. The urethral orifices were normal in appearance and the bladder surface appeared quite normal. There were a few pus cells noted in the catheterized specimen.

Preoperative determination of the urea showed 25 mg. per hundred cubic centimeters of blood.

Under sacral anesthesia a transurethral resection of the obstructing tissue of the internal urethral orifice was performed with the McCarthy resectoscope. Six pieces of tissue were taken starting at 3 o'clock going through 6 o'clock and around to 9 o'clock.

Postoperative convalescence was uneventful and the patient got in excellent immediate and late postoperative result.

Fig. 15—The tissue removed from II B shown in figures 13 and 14.

CASE 3—Mrs. J. L. H., white, aged 72, first seen in April 1937, complained of difficulty in passing urine, a frequency of thirty minutes to an hour during the day and six to eight times at night, urgency and suprapubic pain.

Examination showed a definite stricture of the urethra so that a number 16 cystourethroscope had to be used for the examination. In addition there was observed a pronounced chronic granular urethritis. In spite of regular urethral dilations the patient obtained only partial symptomatic relief. Repeated determinations of residual urine showed from 1 to 3 ounces (30 to 90 cc.) on each occasion.

On Sept. 26, 1937, the patient developed a complete retention and was admitted to Baylor Hospital where examination was carried out under general anesthesia. The stricture had been dilated so that a number 24 cystoscope could easily be introduced. We observed a thickened bar of tissue across the floor of the internal orifice, and it was decided to resect this since there was no other explanation for the complete retention.

With a McCarthy resectoscope only four pieces of tissue were removed from this thickened bar, and a two way catheter was left in for continued drainage of the bladder.

Convalescence was stormy. During the next three days there was an elevation of temperature to 103.5 F. on each

day. Following this however, the temperature gradually subsided to normal and the patient was discharged from the hospital on the tenth postoperative day. At that time she was able to void freely and had no trouble with urinary control.

Fig. 16—Autopsy specimen of Mrs. H. showing bilateral hydro-nephrosis and hydroneurter with trabeculated bladder wall, one diverticulum, two bladder stones, and a prostatic bar, the cause of the entire pathologic picture.

Fig. 17—A closer view of the opened bladder and urethra showing diverticulum, trabeculae, stones, and prostatic bar.

The late result has been satisfactory although the patient still voids one to two times at night and the catheter urine continued to show about grade 1 of pus in the centrifuged sediment.

The pathologic diagnosis of the tissue removed was chronic inflammation of the urethral mucosa.

CASE 4—Miss L. K. white, aged 25, complained of frequency of urination, nocturia, and dysuria. These symptoms had been present for a year in spite of the fact that the patient had been receiving all types of local treatment to the urethra during this time.

At the time of our first examination she was complaining of spasmodic like pain in the urethra and bladder that would occur at frequent intervals and would cause her to void every few minutes. These attacks would last for an hour or two and then she would suddenly get relief. During these attacks she was never able to void more than a few drops of urine, although after the spasm passed she could then completely empty her bladder.

On examination we found the urethra of normal caliber and the urethral mucosa showing only a slight congestion in the posterior portion. There was a thickening of the tissue of the internal urethral orifice involving the entire circumference. The bladder was normal on inspection of the interior and the upper urinary tract was normal.

Under general anesthesia a transurethral resection of the fibrous tissue from the internal urethral orifice was carried out, tissue from the entire circumference being removed in the amount of 3 Gm.

The pathologic diagnosis was chronic urethritis with epithelial hyperplasia.

A catheter was left in for two days following the resection. The patient left the hospital on the fifth day. She obtained an excellent immediate postoperative result. She was last examined one year following her resection and had been very comfortable, although at the time she had mild spells of dysuria that would last for a day or two.

ABSTRACT OF DISCUSSION

DR. NELSON F. OCKERBLAD, Kansas City, Mo.: I have never seen a case of female prostate obstructing or otherwise. This paper of Folsom and O'Brien does excite my interest. I have sometime had this experience. The wife of one of my patients, whom I had resected for prostatic obstruction, has come to me somewhat timidly and secretively to suggest that she thought that she needed the same sort of an operation as she was having the same symptoms and her prostate was undoubtedly at the bottom of the trouble. Residual urine in the female is not particularly rare and is generally due to one of two causes: (1) neurogenic bladder of whatever type and (2) stricture of the urethra. The female urethra is a subject concerning which the authors know a great deal. It has been my experience in dealing with women who complain of trouble in the urethra that in fully one half the cases you do for them the quicker they will get well.

DR. REED NESBIT, Ann Arbor, Mich.: Just eleven years ago in this section Dr. Folsom discussed this same problem and called our attention to the subject. He said that many women have difficulty at the vesical outlet and few have real obstructive lesions there. It is important to realize that in all of the cases reported not only by Folsom but by others in which relief has been brought about by transurethral resection, there have been three definite objective findings which have been of value in diagnosis. First of all there has been residual urine, second there has been trabeculation of the bladder, and third there has been a palpable lesion which could be seen with a cystoscope or a urethroscope. During the past year I have seen 2 women who might fall into this category. They had difficulty with urination. One of them had complete retention of the urine requiring catheterization. Neurologic examination was negative in both of these cases. In both there was residual urine. There was a moderate degree of trabeculation, and on pantoscopic examination a visible bar was present which was not palpable by vaginal examination on the instrument. In these 2 cases we suspected that there might have been a neurogenic contraction of the vesical outlet or the internal sphincter. A procedure was utilized in order to differentiate this point. I believe Alec Hepler first suggested it. A local anesthetic agent was injected

into the lumbar sympathetic, after the manner described by Alton Ochsner for the treatment of inflammation of the vein from phlebitis. One can tell whether this injection is taking hold, because immediately the patient's legs get an increase in warmth. In both cases the visible contracture of the vesical outlet disappeared on cystoscopy, so we were saved the embarrassment of having operated on a functional rather than an organic bar which is something to hold in mind. It is very important that we observe residual urine, trabeculation of the bladder and a palpable lesion. Do the authors advocate prostatic massage in any of these cases?

DR HERMAN L. KRETSCHEMER, Chicago. I agree in part with Drs. Folsom and O'Brien, what I disagree with is the title of their paper. Obstruction at the neck of the bladder in both children and adult females is a rare lesion. However, it occurs more frequently than is generally recognized. Many girls and women with trabeculation and hydronephrosis have as the underlying cause obstruction at the bladder neck. This condition is frequently overlooked and as a rule the patients when consulting the doctor come in late in the course of the disease after irreparable damage to the upper urinary tract has occurred. Therefore it behooves all of us to be on the lookout for these cases to remove the obstruction before damage to the upper urinary tract has taken place. I agree with the authors that the treatment is transurethral resection. The patients belong to this group on whom we have performed transurethral resection. We have had most satisfactory results. The point on which I disagree is that of the selection of the title, namely, "The Female Obstructing Prostate" because it is my opinion that the female does not have a prostate.

DR VINCENT J. O'CONNOR, Chicago. The lesion described by Drs. Folsom and O'Brien has been a matter of interest to me for a long time. I have encountered 9 women with unmistakable mechanical obstruction of the vesical neck. The authors have had the opportunity of studying Kodachrome photomicrographs of the tissue removed by transurethral resection in these 9 patients. The obstructing tissue removed from the patients we have seen has not been of uniform character. Some of these tissues are purely fibromuscular, some are granulomatous or inflammatory and some have a predominance of glandular elements. I agree that the term "prostatism" in the female is quite misleading. We must not confuse these patients with the hermaphrodite or pseudohermaphrodite who actually appear to be female yet have male gonadal tissue. Before proceeding to resect an apparent obstruction at the bladder neck in women it is imperative that we recognize what, if any, part relaxation of the floor of the bladder plays. In cystocele moderate or advanced, there often appears cystoscopically to be an increase in the size of the internal sphincter or vesical neck. The neurologic examination must be negative, there must be both visual and palpable tissue apparently obstructive in character and there must be residual urine that cannot be explained by relaxation of the bladder floor before the indications are clear for transurethral resection of the female bladder neck.

DR A. I. FOLSOM, Dallas, Texas. Those women that Dr. Ockerblad had apparently knew better about what was the matter with them than he did. He said the less you do for them the better. That isn't my experience. Dr. Nesbit's suggestion of a neurogenic contraction of the internal vesical sphincter is a thing which I am not sufficiently familiar with to discuss, but my impression is that the neurogenic disturbance of the internal vesical sphincter is a relaxation. He asked if I massaged these. As a matter of fact I massaged one for him in his own clinic one day and showed him the secretion coming out of the duct. Dr. Kretschmer takes issue with me as to the term. I don't know any better term for it and I don't see any use of quibbling over terms. Caldwell, whom I consider to be as good a pathologist as there is in this country, has definitely gone on record as saying that there is a definite homologue of the prostate. I am surprised that you do not know that Virchow found prostatic calculi in women in the posterior part of the urethra, and if you will look at the article that I first published in 1931 you will find a beautiful illustration of a large prostatic calculus and there are corpora amylacea. I do not care what

you call it. If this is not the right thing to call it we will call it something else, but as a matter of fact, we have no proper term for the condition in the male. Prostatic hypertrophy is not adequate. I think there is no objection to calling this "female prostatism." O'Connor's suggestion about cystocele brings up a thing that I have very definite convictions about. I have many records of women who have been operated on for cystocele, for relief of bladder irritation, and I have then had to go in and clear up a posterior urethral inflammatory lesion and get them well. Now I have no argument, of course, with the gynecologist about doing a cystocele operation of any kind that he wants to do as long as the indications are definitely gynecologic but I believe that the gynecologist who operates on women with bladder trouble and does this repair of the cystocele purely for bladder trouble is going to fail ten times to where he succeeds once.

Clinical Notes, Suggestions and New Instruments

LEAD INTOXICATION FROM A BULLET LODGED IN THE SPHENOID SINUS AND SURGICAL REMOVAL OF THE BULLET

LIEUTENANT COMMANDER CHARLES F. FITCH

MEDICAL CORPS, UNITED STATES NAVY, RESERVE, RETIRED

The present war era will undoubtedly result in an intensified study of the effects of retained lead and a brief review of the possibilities in such cases is apropos at this time. Lead intoxication from absorption by way of the mucous membrane of the nasal mucosa is rare. Secondly, the removal of a bullet lodged in the sphenoid sinus is an unusual problem of surgery.

There has been some change in opinion from that expressed by Ambrose Pare in the sixteenth century. "Experience

FIG. 1.—Anteroposterior view of the skull showing lead fragment at the point of entrance at the superior margin of the left orbit. The main body of the bullet may be seen lodged in the left sphenoid sinus.

teaches us that lead (which some say is poisonous because mercury is derived from it) can remain a long time in our bodies without causing any corruption as we can recognize

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.
1. Pare, Ambrose. *Oeuvres complètes d'Ambrose Pare*. Paris: M. L. gigne edition 3 347 1840 1841.

in those cases of arquebus wounds where the ball has remained in the flesh a space of three, four and even ten years, and has moved from top to bottom without causing any putrefaction or harm which demonstrates that [lead] has no poisonous qualities but rather possesses a familiarity with our nature." In contradistinction to Pare's opinion, there were physicians of the Middle Ages who definitely associated colic and palsy with lead. To Tanquerel des Planches² goes the credit of first correlating the manifestations and symptoms of lead intoxication.

The earliest reported case of plumbism caused by the retention of lead bullets was made by Bronvin³ in 1867. Willard Machle⁴ made a careful study of more than 40 cases and published a monograph on the subject of lead poisoning from retained bullets. This series, as presented by Machle shows 3 cases of retention and of the removal of bullets from the head and brain, but no reference has been found in the total literature of the removal of a bullet from the sphenoid sinus.

It is stated by Cecil⁵ that subcutaneous or intramuscular deposits of lead enter the blood stream so slowly that intoxication from bullets, if it occurs at all, is very rare, but it is now recognized that lead may be absorbed from the gastro-

upward outside the frontal bone and a large fragment entering the orbital fossa. The fragment lodging externally was mostly removed. The patient further stated that he was unconscious and delirious an unknown period of time and was not expected to live for the first month after the accident. He was confined in the hospital for three months and returned to work four months after the accident. The fragment entering the orbital fossa was disclosed by roentgenograms to have lodged in the left sphenoid sinus from which he was told the removal would be fatal.

During the next several years he noted but few symptoms referable to the accident. He occasionally noted some vague "distress" and a weird feeling in the vertex and experienced half-hour attacks of panting about once a month. No further signs or symptoms were observed until about two years before I saw him (eight years after the accident) when he began to note progressive aching in both legs which he ascribed to long hours of work. This aching of the legs had increased during the last two weeks to the degree of being unbearable. The patient also reported split second flashes of unconsciousness during the last two years, occurring about once every three to four weeks.

The patient consulted Dr. Leonard Thompson of San Pedro about six months before for a general physical examination mainly because of the aching of his legs and a feeling of general weakness and extreme constipation.

At that time physical examinations and roentgenograms of the chest were reported negative. Two weeks before I saw him the patient experienced faintness, panting and chilliness which lasted for ten minutes and was followed by trembling of the upper extremities. Consulting his physician again he was referred to me. On the basis of physical examination and x-ray study Dr. Thompson suspected lead intoxication.

Dr. Cullen Ward Irish saw the patient in neurologic consultation. Dr. Irish reported that in his opinion there was some toxicity of the central and peripheral nervous systems from the absorption of lead for the past ten years. Subjective and objective findings were as follows: Severe aching was experienced in the calves of the legs and across the shoulders and radiated into the upper extremities. There was little involvement of the motor nerves as is frequently seen in lead poisoning and no wrist or foot drop. Atrophy in the muscles of the upper and lower extremities was obvious. This hypotonia and atrophy in the calves was ascribed to lead poisoning of the anterior horn cells of the spinal cord. The spasticity which appeared when the patient was sitting, standing and walking indicated that there was also some involvement of the spinal pyramidal tracts. There was some optic atrophy due undoubtedly to lead absorption. The scotoma as found in the left retinal field was undoubtedly caused by the initial bullet trauma. The brief losses of memory described by the patient were probably petit mal epilepsy which attacks are not unusual in lead absorption. It was apparent in the recent past that there had been a rapid progression of symptoms, and in the neurologist's opinion the remnant of bullet in the left sphenoid sinus would have resulted fatally had not the nidus of absorption been removed.

Dr. Irish ordered the use of calcium by mouth and ven to attempt to fix disseminated and free lead in the bones.

LABORATORY OBSERVATIONS

The major physical and laboratory manifestations of plumbism as given in the series presented by Machle⁴ are shown in the accompanying table. The comparison is made with observations set down in the last column on my patient.

The present case is exceptional in the fact that the laboratory tests for lead were all negative; however, the gastrointestinal, joint muscle and central nervous system manifestations were severe and classic for lead intoxication.

Fig. 2—Lateral view of the skull showing the fragments of lead in the orbit and the bullet on the floor of the left sphenoid sinus.

intestinal tract, from the respiratory tract and also from the mucous membrane of the nose and mouth.

REPORT OF CASE

J. W., a man aged 34, was assisted into the office, Dec. 23, 1941, by a friend. His legs apparently were not able to accept his body weight, he was pale, emaciated and apprehensive. He carried roentgenograms in his hand which he presented with the abrupt question "Can you take this bullet out?" When answered with a cautious affirmative he demanded that the removal be done immediately, stating that he did not believe he would survive if this effort should be deferred. When advised that the operation in itself might result in mortality he was indifferent and continued to be insistent on immediate effort even the day before Christmas. The attitude of the patient was impatient, irritable and mandatory.

The relevant history leading up to the present time was as follows:

In September 1931 the patient was engaged in target practice at a shooting gallery where the 0.38 caliber revolver which he was using accidentally discharged. The bullet struck the left supraorbital ridge, where it split a small part passing

OPERATION

The approach to the left sphenoid sinus was done by the submucous route. The submucous resection was carried farther posteriorly from the bony septum and the mucous membrane dissected from the anterior face of the sphenoid sinus. Sewall's sphenoid chisel was used to remove the anterior wall of this sinus, and the opening was enlarged with the Faraci sphenoid punch. With focal illumination, after suction, the edge of the bullet fragment was seen and grasped with the Hartmann forceps and rocked back and forth until it was felt to be free, and then the bullet was removed. A permanent opening was made through the mucous membrane of the anterior wall of the sphenoid by nasal approach. The mucous membrane was approximated and gently packed in position. There was little bleeding, and the patient made an uneventful recovery with definite improvement in the nasal breathing following the incidental submucous resection.

COMMENT

The patient at this time, approximately five weeks after the operation, is remarkably improved in general health, has discarded in turn crutches and double cane and now carries but one cane, which he says he feels he will soon dispose of perma-

Summary of Forty Reported Cases

	Machine Cases			Present Case
	Interval to onset	12 days to 45 years less than 1 year	12 to 10 years	5 years
		10 or more years	17 (6)	
Location of missile		Bone and joint	24 soft tissue, 13 (3*) bathed with synovia	8 Sphenoid

nently. The patient has lost his irritability, his petit mal attacks and his extreme constipation and says that he now feels mentally and physically more adequate to carry on than at any time since his initial accident.

CONCLUSIONS

1. A man aged 34 has carried a lead bullet in the left sphenoid sinus for ten years as the result of the accidental discharge of a revolver.

2. Symptoms of true lead intoxication began approximately eight years after the accident and were characterized by nausea, extreme constipation, arthralgia (severe in the inferior extremities), spasticity of the muscles of the inferior extremities when at rest and some toxic dementia.

3. Laboratory findings were not positive as was expected.

4. The bullet was removed by submucous resection approach. No complications were encountered.

5. The patient has improved rapidly relative to all symptoms six weeks after removal of the bullet.

6. A neurologist has advised giving large amounts of calcium to fix free lead that may be present in the tissues.

ANDREAS VESALIUS AND THE "FABRICA"
1543-1943

ARTURO CASTIGLIONI

NEW HAVEN, CONN.

Among the classics of the Renaissance which truly represent the struggle and glory of that period, the *Fabrica* of Vesalius holds a foremost place. Written by a learned humanist and an indefatigable research worker, a great physician and a fine artist, it is still worthy of our admiration as a magnificent product of science and art.

Andreas Vesalius was born in Brussels on Dec. 31, 1514 and numbered many distinguished physicians among his kin. In early youth he began the study of anatomy, which he pursued at Louvain and Paris. He soon recognized that the professors, who taught out of Galen and relegated dissection to barbers, could neither teach nor even learn. Convinced of Galen's infallibility, they shunned personal observation and ignored research. When war between the German emperor and the king of France paralyzed the University of Paris, Vesalius returned to Louvain and then went to Italy, where anatomy was taught actively in many schools. He resided first in Venice and then in Padua, where on the sixth of December 1537, the day after his promotion to Doctor of Medicine, he became professor of surgical medicine and anatomy at the school which the proud republic of Venice considered as its most precious treasure. Padua was the center of the scientific thought of the Renaissance, and the young Flemming was soon its most popular teacher.

Within five fervid years his life's great work was begun and ended. In the year 1537 his first writing, a Commentary on Rhazes, was published in Louvain. In 1538, in order to offer a correct guide for students, surgeons and artists, he published the six *Anatomical Tables* three of which had been drawn by his friend and countryman Stephen van Calcar and three by himself. These were a definite innovation in anatomic illustration and were promptly plagiarized. In 1540 he published the Commentaries on the anatomic books of Galen. In this same year he began to collect observations and prepare the drawings for his master work, the *Epitome* and the *Fabrica*. The first was planned as a guide to anatomy for common people and at the same time acted as an announcement for the more extensive work, which came to light in a splendid edition by Oporinus in Basel on May 5, 1543.

At the beginning of his anatomic teaching Vesalius felt the desire to recall from the dead the science of the ancients, which he believed to have been misunderstood and misinterpreted by their followers and their commentators. It was the current tendency of the Renaissance to return to the pure sources of the classics and to free the schools from the teaching of the Arabs. Vesalius said explicitly that his aim and his hopes were that anatomy "could reach such a point to be equal to that of old." The respect for the ancients was alive in him. At Padua, where he was charged "by the illustrious Senate of Venice, which is far the most liberal in the endowment of the higher branches of learning, with the teaching of surgical anatomy," he devoted the greatest effort to his investigations "in a way that nothing could be found in his procedure that fell short

of the traditions of the ancients" The Anatomical Tables (1538), which had to replace the traditional fugitive sheets which were very popular among students and physicians, brought the first attempt of reproductions from direct observation But Vesalius still accepted the galenic anatomy or at least he had not yet corrected many of its mistakes The anatomy of the liver, of the uterus, of the bladder, of the sternum is still galenic But he had begun to dissent, trying first to rely on the authority of pregalenic scholars, believing that the Alexandrian anatomists, having dissected human bodies, had really possessed a better knowledge of anatomy The study of Galen's work which he made with the greatest diligence in order to prepare the new edition of the anatomic books, published in 1540 by the Giunta in Venice in a splendid and very accurate form, gave the proof of the astonishing fact that "in the manifold and infinite divergence of the organs of the human body from those of the monkeys Galen had hardly noticed anything except in the fingers and the bend of the knee" Now, definitely sure of this fact, in the first edition of the *Fabrica* the young professor of anatomy took his stand He knew and clearly proved and affirmed that it was impossible to rely on Galen and that the story of anatomy had to begin anew He rebelled against the anatomists who asserted that in Galen's books not even the slightest error could be found, that any other book on anatomy was absolutely useless and had to be condemned to the stake He fought against the absurd assertion that, if some differences from Galen's description should be found in the anatomy of human bodies, these had to be ascribed to the changes to which the organs may have been subjected in the course of time, but not to an error of the Prince of Physicians, which was inadmissible Vesalius could not countenance servile adherence to Galen, which meant renunciation of independent observation and free judgment He starts from anatomy, which he correctly considered the foundation of medical knowledge

The program and the original conception of the work are given by the title itself¹ It was conceived as a complete system of anatomy ordered in an organic way and based exclusively on independent personal observation The dissection is no longer a pure formality, the barber or the surgeon has nothing more to do in the anatomic theater The professor himself, without the help of any book, has to dissect and teach The frontispiece of the *Fabrica*, where the teacher appears in the act of dissecting and explaining, is an eloquent declaration of principles

The text of the book is in perfect accord with this program The exposition of the subject is ordered so that the reader may obtain an exact knowledge of all structures There are no longer isolated descriptions of single organs or claims to new discoveries The whole anatomic structure of the human body is examined and studied in its integrity Every organ, every bone, every muscle, every vessel finds its correct place in the general design, its denomination, the exact description of its anatomic form, the explanation of its functions

The *Fabrica* is the book of a man of the Renaissance who, having started from humanism with a sound knowledge of Greek, Latin and Arabic authors, had emancipated himself from the tradition and was fully aware of the originality of his observations and conclusions The personality of the teacher is constantly

predominant The direct communication with the pupils is evident Vesalius presented first his own observations, then the mistakes of other authors and his corrections, never posing as an authority but always inciting the reader to examine to control and to judge by himself

The illustrations of the book are an essential part of this work Stephen van Calcar was a fine artist and a keen observer whose name deserves to be perpetually bound to Vesalius's glory, we know that every single drawing was made under the guidance of Vesalius, who took great care in supervising the engraving and discarded the pictures which he did not like or which had not come out satisfactorily

The figures of the *Fabrica* belong to the most interesting pages in the history of art in the Renaissance The men in Vesalius's book are alive, their muscles are in action The general figures are in attitudes which remind one of the Antinous or the Aphrodite of classic times, sometimes meditating on the problem of life or death as figures of a great drama who show the inner secrets of their life I may say that the animating spirit of the Renaissance has revived the corpses of the criminal or the prostitute made them appear on the beautiful background of the Italian landscape and invested them with a touch of beauty and of glory They form the link between the free and joyous life of the Renaissance and scientific thought the eloquent witnesses who stand forever as the proof of the *Vesalian* struggle

There are books which play in history the role of battles Vesalius's *Fabrica* was such a battle, fought by one man alone against a host of enemies, a battle from the first to the last page, sometimes fought with a chivalrous respect for the adversary, sometimes with strong blows

With this book, in the twenty-eighth year of his life, Vesalius reached the climax of his activity and deliberately threw himself into one of the fiercest battles which ever was fought for independence of thought against tradition and authority The world of the scientists was upset, in Paris Vesalius's teachers were the first to attack their former pupil, in Germany Galen's authority was still holding sway, in Italy not all of Vesalius's pupils accepted the truths he had proclaimed A great number of books of pamphlets, of letters addressed to scientists and princes found their way into publicity in order to undermine the position of the rebel Vesalius, deeply hurt, gave a prompt and sometimes violent answer to his opponents, then he left his school, burned his books and among them destroyed some works not yet published He became the physician of Charles V, followed the emperor in his journeys and later became physician to Philip II of Spain The history of the last years of his life, of his pilgrimage to Jerusalem, of his death on the island of Zante where he landed ill, unknown and abandoned, has often been told, but the mystery of his end has not yet been solved One thing is sure, however after the publication of his anatomic books, his work as teacher and as anatomist was brought to an end From the first day when he began his public dissections at Padua until the last moment of his life, he stood courageously against all his enemies, answering with good arguments He never recanted one word of what he had written, never changed his attitude and always maintained full responsibility for his assertions and absolute truthfulness to his principles

1 *De humani corporis fabrica libri septem*

The *Fabrica* was published contemporaneously with another revolutionary book, written by another learned physician and former student at Padua—the *Revolutions of the Celestial Bodies* by Nicolas Copernicus. Vesalius's work found its way notwithstanding the violent attacks, the vulgar offenses, the accusation of heresy and in spite of the lukewarm hypocritical eulogists and the brazen plagiarists. The contests and the discussions which arose at the time of its publication are nowadays forgotten and the names of Vesalius's enemies, the great professors who embittered his life and were respected as infallible authority, have only a remote historical resonance, but the date of the publication of the *Fabrica* marks a definite event in the history of science, the beginning of scientific anatomy.

HANDBOOK OF NUTRITION XXIII

MEDICAL EVALUATION OF NUTRITIONAL STATUS

H. D. KRUSE, M.D.
NEW YORK

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed.

Evaluation of nutritional status is designed primarily to determine whether a person is malnourished. At once this stated aim raises several questions: What is malnutrition? What are its specific manifestations? If it is to be recognized, its characteristics must be known. Which of these should be selected as a basis for detection? Assuredly the methods must be founded on qualities which adequately represent malnutrition.

The very name evaluation of nutritional status indicates that the procedure includes something more than placing a person in either of the two categories: well nourished or malnourished. If malnutrition is found it is also desirable to ascertain its severity. Malnutrition occurs in all degrees. If a sufficiently large number of persons at random were examined by the most sensitive and specific methods, their nutritional condition would form a continuous series from perfection to extreme malnutrition. It is necessary to classify the series into degrees, to establish standards and to have a scale of rating. Then a person's status may be compared with standards and rated accordingly. Here we are concerned with something more than detection of malnutrition; we also want to measure it. For this is needed a system of examination which is not only specific but also sensitive. The methods must permit distinction of fine differences in measuring malnutrition.

In answering the questions: What is malnutrition? and What items should be examined? it will be seen that the concept of malnutrition, the methods and criteria of evaluating it are inseparably linked. For the methods and criteria reflect the views on the nature of malnutrition. All three aspects have been undergoing an evolution during the past half century.

CROSS SECTIONAL METHODS OF EXAMINATION

Most of the methods of examining for nutritional status have been devised for application on large groups of persons, especially school children and army recruits.

Here the examination is a screening process that will both separate and rate the malnourished.

One of the early methods, the physician's estimate from inspection, has undergone a series of changes. In 1905 Koppe¹ regarded nutrition as one of eight components of constitution. To him nutritional status was indicated by the amount of panniculus adiposus. Each of the constitutional components, including subcutaneous fat, was rated in five grades. The grades for all components totaled and averaged gave the score for constitution. Obviously nutritional status was completely obscured in constitution.

In 1908 Gastpar² used three items for judging and five grades for designating nutritional status. Pupils were divided into two groups, anemic and nonanemic, according to the circulation in cutaneous and mucous membranes. The first group was then divided into two, the latter into three subgroups according to musculature and subcutaneous fat. The grades were: good, fair, poor, fair and anemic, poor and anemia.

Hogarth³ appraised nutrition as part of physical condition. The latter was composed of three factors: physical stature, general nutrition, circulation in the superficial membranes. Each factor could be rated in five possible grades. Musculature and panniculus adiposus were the basis of judgment for nutrition. The possible ratings were: (1) excellent muscular development, (2) well nourished and healthy, (3) medium, (4) thin or fat and flabby tissues, (5) very thin. But nutrition lost much of its identity in the three figured score for physical condition.

According to Howarth⁴ physical state is evidenced by height, weight and nutrition. His basis of judging nutrition was: skin and mucous membranes, hair, alertness, muscular tone. There were three grades of nutrition.

In the Dunfermline system⁵ the following points were taken into consideration: height and weight in relation to age, general appearance, mucous membranes, skin and subcutaneous tissues, muscular tone and development, facial expression, carriage, movements, voice, interest and attention. At first nutritional status was recorded as good (above average), medium (average) and bad (below average). Later "the nutrition of the healthy child of good social standing" was the basis of classification, being given the rating: excellent. When nutritional status just fell short of this it was regarded as good. When it was on the borderline of serious impairment it was designated as "requiring supervision." When it was seriously impaired it received the notation "requiring medical treatment."

Against the systems of evaluation by inspection there was considerable criticism. In a frank critique the London County Council report⁶ for 1909 pointed out serious difficulties. Anemia was so complicated by

complexion that it was difficult to assess by inspection. Furthermore, it stated, the physician himself introduced a large personal element.

Indeed, the shortcomings of the inspection methods were numerous and serious. At first nutrition was overshadowed as a component of constitution or physical condition. But, even when nutritional status was the specific and sole objective, clinical examination in practice showed lack of uniformity and agreement. The general criticism was that it failed because of subjectivity in judgment. There are reasons for much of this subjectivity. As has been noted, there was no agreement on items regarded as indicative of nutrition for judgment of status. Then too, standards were relative rather than absolute. Laveran⁷ remarked that estimate of status depended on comparison with variable or unsatisfactory standards. Conditions just previously or most frequently seen influenced the rating assigned to a person. Moreover, there was much variation in number and names of groups, i.e., in rating scale. But even when all these points of variation were fixed, there was still much disagreement. When a group of children were examined by several physicians, using the same items and scale, there was still no uniformity in the ratings.⁸ Derryberry⁹ stated "Whether a child is rated as malnourished or not depends more on the physician who is the examiner than it does on the actual condition of the child." It became clear that even under rigidly controlled conditions there was a large element of subjectivity in the physician's judgment.

In the need for an objective method of judging nutrition a new approach was taken. Since normal growth is a manifestation of satisfactory nutrition, growth was taken as a measure of the nutritive state. The immediate question then was: How shall growth be measured?

As weight and height had been used to follow growth and development, they were used to measure nutrition.¹⁰ They were referred to each other, and individually or in combination to age: weight for age, weight for height, weight for height and age, and height for age. Standard weights were derived from statistical analysis of data collected on children supposedly in good nutritive condition. These standards were presented in reference tables.¹¹ In other instances weight and height were used in a simple ratio to give an index number which could be compared with a standard.¹²

As early as 1909 Oeder¹⁰ and Oppenheimer¹³ pointed to inaccuracies in using weight as the measure of nutrition. Gradually the reasons became clear. For one thing, as it was by no means certain what consti-

tuted normal growth the suitability of available height and weight standards was open to question. Scarcely less difficult was the question: How much deviation from average should be allowed for individual variations? These points led to much cross criticism. But troublesome as they were, there was still a more serious criticism.

From a study in which there was no more underweight in a group on a poor diet than in a group on a good diet¹⁴ the validity of weight as an index of nutrition was considerably shaken. Indeed selection by weight was much less accurate than by clinical examination¹⁵ when each was referred to dietary data. As might be expected selection by weight and by clinical examination when compared directly showed serious disagreement.¹⁶ In this discrepancy the clinical examination, for all its acknowledged shortcomings, was regarded as superior. Unfortunate as were the instances when children were diagnosed as malnourished by weight but were well nourished according to clinical examination, much more serious were the instances when children rated by weight as well nourished showed pronounced signs of malnutrition. It was evident that methods employing weight as the measure were inaccurate for estimating the state of nutrition.

In retrospect it is seen that unwittingly the enormous misdirected labors over many years in using weight were based on a fallacy in logic. Because persons showing pronounced deviations in weight are malnourished it was inferred erroneously that persons not showing these deviations are well nourished. Actually, on the basis of weight it is not possible to characterize normal nutrition. Nevertheless weight was extensively used in this country until 1930, when the mass of accumulated evidence against it overwhelmed it.

Meanwhile, as soon as the defects of methods using weight in association with height and age as a basis of judging nutrition became evident steps designed to remedy them had been taken. Most attempts were aimed at supplying new standards in the hope of making the methods accurate. These modifications developed simultaneously, took several lines.

One type was the determination of standards of weight in normal nutritive condition. In attempting to appraise the nutritive status of adults by weight Oeder¹⁷ encountered difficulties similar to those in using the method during growth. He attempted to find the normal nutritive condition so that he might determine the range of body weight associated with it. Of bodily constituents, fat was found to be the one

altered most extensively in starvation and adiposity, representing extremes of nutritive disturbance, and the one reacting most sensitively to change in nutrition. Consequently he regarded fatty tissue as the index of nutritive condition. He listed four signs of normal nutritive condition, including a definite thickness of fat layer on the abdomen. He recorded the normal range in the thickness of this fat layer and the corresponding body weight. Then his line of reasoning led him to displace use of weight by measurement of the fat layer on the abdomen.¹⁸

Another kind of attempt to improve the use of weight methods was the calculation of normal standards in relation to physique. By 1912 it was becoming apparent that variations in type of body build had to be considered in judging growth by weight and that these variations had to be taken into account in the prediction of normal weight. During the latter half of the nineteenth century several index numbers derived from formulas containing various bodily measurements had been used in following physical development or expressing body build or constitution.¹⁹ Some of these contained weight as a factor. As Bornhardt²⁰ pointed out, transposition in his equation made it possible to solve for weight. Several other formulas or ratios, most of them patterned after the earlier models, were proposed for determination of theoretical weight with which actual weight could be compared.²¹ In other instances the procedure was to measure body build by dimensions other than weight and to note the weight associated with them.²²

Still another approach ushered in the use of nutritional indexes. Recognizing the errors in judgment by weight and the subjectivity of a physician's inspection, Oppenheimer in 1909 devised a method that would be objective but have a clinical basis.²³ He argued that physicians, recognizing that certain bodily parts reflected malnutrition more sensitively and accurately than does weight, based their judgment subconsciously on the relation of these parts. Each physician, he asserted, tended to rate the nutritional status according to his

estimate of musculature and adipose tissue. But individual judgment of these parts differed appreciably because of the difficulty in making proper allowance for the complicated differences in body build. To overcome this difficulty, Oppenheimer selected three bodily dimensions which reflected the relation of body parts decisive in the physician's estimate and which could be objectively measured. From these three dimensions he propounded two formulas: one gave the measure of nutrition, which increased with age and growth, the other gave the quotient of nutrition, which was influenced only by nutritive condition. Twenty-five years later the same rationale²⁴ and almost the identical measurements were adopted in working out the ACH index,²⁵ except that a different relation of measurements and a reference table were used.

Attempts to make allowance for variations in body build in the appraisal of nutritional status took another direction. With the realization that the ratio of height-weight failed to indicate accurately whether the amount of muscle and fat corresponded to the skeleton, other sets of dimensions were suggested. From anthropometric studies of growth Pirquet²⁶ found that weight referred to sitting height in the form of a ratio yielded a numerical index, "pelidisi," which he regarded as an objective measure of nutritive condition.

At the same time the widespread prevalence of malnutrition in Austria and Germany during World War I created an emergency; the American War Relief Commission and Quakers² desired a rapid and objective method of selecting the children needing supplementary food. Ratios containing various physical measurements which had been used for many years to express body build, constitution or physical fitness were turned from their original purpose and were applied, either unchanged or changed, as measures of nutrition.¹⁰ Several new but similar ratios appeared, some containing weight as an item. In all of them a change in a measurement and therefore in the resulting quotient, the index number, was regarded as indicating a shift in the nutritive status. Since these equations contained measurements presumed to reflect body build, they were regarded as more sensitive and accurate than weight-height in evaluating nutritional status.

But evidence showed that all these indexes, formulas, equations and ratios aimed to refine or replace the height-weight method had its same defects.²⁸ They

were vulnerable to the same criticisms. Actually, they revealed more about body build than about nutrition. Naturally the application of these methods to adults was based on other considerations than growth, but the results were just as unsuccessful as those on infants and children.

LONGITUDINAL PROCEDURE

In contrast to the preceding cross sectional methods of examining growth, the longitudinal procedure of following the growth curve was also suggested as a measure of nutrition. Greenwood²⁹ proposed that the percentage growth per year in height and weight, respectively, be the standard of comparison. Failure to increase in weight at a given rate would bring a designation of malnutrition. According to one criterion, lack of gain or loss in weight for each month of three successive months was cited as a means of screening children with poor growth.³⁰ It has been asserted that the weight curve is the most accurate measure of growth.³¹ This method has been successfully used in animal experiments in nutrition. But the animals were inbred and selected. Besides, they were subjected to dietary deficiencies with pronounced interference with growth. For both human beings and experimental animals, the so-called normal growth curves have changed over the past three decades. No one knows whether greatest growth has yet been obtained, whether greatest is optimum, in short, what optimum growth is. And no one knows how slight a deviation in growth curve should be regarded as malnutrition. Thus the very same objections to use of absolute weight may be leveled against the use of the growth curve.

Recently there appeared a method which combines the longitudinal and cross sectional procedures permitting application of either.³² A grid prepared from height, weight and age is purported to give ratings during the period of growth on physique, development, nutrition and physical status. The slope or gradient of the developmental curve is said to give a measure of nutritional status. If measurements are limited to a single observation, a tentative estimate of nutrition can be made. Since height, weight and age are the only measurements used, it is similar to previous growth methods and it may therefore be open to the same difficulties and objections. Its class limits, admittedly arbitrary, are different, but it remains to be seen whether they are free of the defects which have restricted the use of all growth methods.

There is no desire to disparage or discredit the proper use of deviations in growth, shown by height or weight, as an indication of malnutrition. It should never be forgotten that an obvious and unequivocal disturbance in weight—or other measurements—indicate serious malnutrition. About this there has never been an argument. Used within this limitation—and this a serious limitation—a weight method has distinct value. It is when it is used beyond its restrictions that its fundamental defects emerge. It breaks down at the

very point at which it is most needed, the borderline zone. It does not satisfactorily separate the slightly abnormal from the normal. Then when the scale is set at unequivocal limits the method is not a sufficiently sensitive screen for detecting malnutrition. In addition, for other reasons it will be seen that it is too inadequate and insensitive to serve as the primary screen of malnutrition.

In 1935 Dr. Roberts³³ wrote "It should be understood at the outset that the whole question of the use of growth criteria for assessing nutrition has been undergoing severe criticism in the last few years, and most of the commonly used methods have been largely discredited. We are indeed at the moment in a situation where we have lost confidence in the old methods and as yet have nothing new that is satisfactory to take their place." When this was written, little was at hand. But developments were in the offing. Through new knowledge nutrition had already extended into a new and vast domain. Among its many practical aspects, it opened a new and different approach to the evaluation of nutritional status. In the last few years, progress in this direction has brought forth new methodologies and has accentuated the distinct and fundamental limitations of previous procedures based on growth.

DEFICIENCY DISEASES

Following Eijkman's experimental production of beriberi by diet in 1897, Grijns formulated the conception of deficiency diseases.³⁴ He showed that certain foods contained an unknown essential substance which cured or protected against beriberi. When foods lacking the essential were eaten, beriberi resulted. It was clear that deficiency of an essential substance in food produced disease. To this substance Funk gave the name "vitamine."

It had long been known that calories were necessary for growth and maintenance, for with insufficient caloric intake, impaired growth or actual loss of weight, i.e., undernutrition, ensued. During the decade 1912-1922 it was found that a series of chemically unidentified substances, present in very small amounts in natural foods, were likewise essential for growth and maintenance. When the diet was deficient in any one of them, retarded growth or actual decrease in weight took place.

In the same period it was further shown that the "vitamine" protecting against beriberi was identical with one of the unidentified substances indispensable for growth. Then from animal experiments it was found that lack of each of the growth substances resulted in a separate specific disease which had its analogue in man. Thus scurvy, xerophthalmia and rickets were found to be deficiency diseases, each arising from lack of a different substance. In this dual role each substance was essential not only for prevention of these diseases but also for promotion of growth. As additional essential substances were demonstrated, it was noted that a deficiency in each not only impaired growth but also produced a specific disease. More recently, pellagra and ariboflavinosis have been identified as defi-

34 The developments leading to the modern concept of dietary essentials are reviewed in the book by E. V. McCollum, Eliza Orent Keiler and H. G. Day. *The Newer Knowledge of Nutrition*, ed. 5. New York: Macmillan Company, 1939, chapter 2, pp. 15-31.

ciency diseases. Thus it has been demonstrated that lack of each essential substance produces a specific deficiency disease.

According to accepted nomenclature, each substance came to be designated by the generic name vitamin and an alphabetic letter. Thus xerophthalmia, beriberi, keratitis, pellagra, scurvy and rickets, the major deficiency diseases which historically have occurred in epidemics and endemics, resulted from lack of vitamins A, B₁, B₂, P-P, C and D respectively. With the chemical isolation and identification of the vitamins, it has been convenient to give each a more descriptive name as follows: B₁, thiamine, B₂, riboflavin, P-P, niacin (nicotinic acid), C, ascorbic acid. Vitamins A and D have yet to be given such a designation.

Meanwhile the concept of deficiency diseases had been extended to embrace those disorders arising from deficiency of essentials other than vitamins, e. g. protein, calcium and iron. Thus, lack of an essential, whether a vitamin, protein or mineral, produces its own particular and specific deficiency disease.

From these facts may be formulated the principles epitomizing the newer knowledge of diet and nutrition: (1) a number of essential substances are contained in food, (2) a deficiency of each essential substance in the diet interferes with growth and maintenance and induces a disease, (3) the relationship between the nature of the dietary deficiency and of the resulting disease is characterized by specificity. These principles have had a profound influence on nutritional science, especially the concept of nutritional status and means of appraising it.

This knowledge of dietary essentials gave a new approach to the detection of malnutrition. It suggested surveys in which diets were analyzed for deficiencies in the essential items.³⁵ This procedure is based on the assumption that evidence of dietary deficiency indicates impaired nutritional status, usually in the form of deficiency diseases. Despite its many possible sources of unavoidable inaccuracies, the dietary method yields highly informative results. But it has several drawbacks. It is costly, laborious and time consuming. By the time the data are collected and analyzed, the information is obtained many months after it is needed. Then too, it reveals only the most recent dietary habits. Fourthly, its evidence on malnutrition is indirect. Fourthly it indicates only the malnutrition due to dietary deficiency. Nevertheless the information derived from it has been helpful, since deficient diet is the most frequent cause of malnutrition. To furnish information on cause is really its principal use. This method has shown that there is nationwide consumption of deficient diets³⁶ and suggests that there is widespread prevalence of malnutrition.

Along with the recognition that dietary deficiencies produce specific diseases came a period of closer study of these diseases leading gradually over the years to improvement in their detection. At first before their etiology was known these diseases, since they mostly occurred in combination in the same person, were not clearly differentiated and were therefore frequently confused. In time the major deficiency diseases were

separated by their main characteristics and several accompanying signs. Even today this work of resolving deficiency diseases into pure form continues. Through inducing the experimental form and through curing the natural form by pure specific therapy, it has been possible to elucidate much about the specific and characteristic signs, the sequence of events and the site of early lesions in each major deficiency disease. In all this, animal experimentation has given many valuable clues. As a result, our knowledge of each deficiency disease in its acute manifest form has been greatly extended and refined. Not a few treatises have been written on these diseases. The older books contain very complete descriptions, although many points must be interpreted in the light of latter day advances.³⁷ Recent books and articles present newer developments.³⁸

But with all this knowledge the occurrence of deficiency diseases in this country has not been generally noted except in city hospitals or endemic regions. Although nationwide dietary inadequacies have been revealed by surveys, frank deficiency diseases on such a scale have not been seen. According to their concept, clinicians rightly assert that they do not see deficiency diseases. But they are incorrect in concluding that there is no widespread prevalence of them. What are the reasons for this apparently irreconcilable conflict between the evidence from dietary surveys and from clinical observations? It is probable that many classic cases pass unrecognized. But even if these were detected and included, the statistics on the prevalence of deficiency disease would not come near approaching the figures on faulty diets recorded in surveys. There is a more significant reason for the seeming discrepancy. In assertions by clinicians that deficiency diseases are not generally prevalent, the traditional severe acute form

has been meant. In this country this classic form is relatively infrequent, instead, the deficiency diseases are present in other forms.

The predominant clinical point of view has carried the concept that a deficiency disease begins or has its significance when it becomes perceptible, usually on simple inspection. Often all or most signs must be present. Clearly that point is not the beginning of the disease. Rather, the disorder is already well advanced before it is diagnosed. Such a practice does not detect the disease in its early or mild form. Over the years, numerous physicians have recognized this point.

Several early investigators attempted to divide the course of scurvy and pellagra into stages, they noted the earliest stage and its characteristics. Some, like Roussel,³⁹ interested in early diagnosis, set down their observations on the earliest sign, stressing the importance of discovering the site of initial change. Moreover, they distinguished a period before the disease proper appeared, before its well known signs were fully developed. As early as 1541 Echthius⁴⁰ enumerated symptoms by which "an approaching scurvy might be foretold", in 1567 Wierus⁴¹ described similar observations. Many subsequent observers recognized a prodromal, incipient or latent period in both pellagra⁴² and scurvy.⁴³ Added still later were the names *forme fruste*, *prepellagra* or *prescurvy*, *subclinical state*. About 1917 other investigators conceived that a deficiency disease like scurvy might exist below the level of clinical detection by any sign, but to this state they applied names already carrying other connotations. Thus several names were applied to the same state, conversely,

several states were designated by the same name or names. In scurvy Hess⁴⁴ drew distinctions which defined these several concepts. He recognized three types of scurvy: the florid, with well developed signs of the full blown condition, the subacute, the commoner form, presenting a group of incompletely developed symptoms, the latent resulting from a negative balance in vitamin C during the period prior to the onset of clinical manifestations. In view of the importance previously attached to weight as an index of nutritional status, it is significant that Hess emphasized the normal weight of children affected with subacute scurvy.

At the same time it was recognized that scurvy might be observed in still another state, the so-called monosymptomatic state.⁴⁵ Cheadle⁴⁶ in 1878 had forecast this eventuality. This occurrence has been confirmed not only for scurvy but also for pellagra. During the last decade numerous epidemics or instances of gingivitis⁴⁷ and glossitis⁴⁸ demonstrated to be attributable to deficiency in ascorbic acid and niacin respectively have been observed. Some investigators have distinguished degrees of one sign in avitaminosis C.⁴⁹ Despite the differences in concepts about the several states and the lax use of terms applied to them, all investigators have agreed that most deficiency diseases occur in these states.

EARLY DIAGNOSIS

In recent years there has been a distinct trend toward early diagnosis of all diseases. It has been recognized that a disease starting with internal manifestations cannot be seen and may yield no signs until it is far advanced, even more so if the lesion is in a silent area, that a disease with early external signs may pass unnoticed into an internal phase or that disease with a persistent or progressive external lesion may develop to a considerable point below the level of perception. In short, most disease has reached the advanced state before it is detected by the unaided senses, its early or mild stage develops unobserved.

The trend to diagnosis of early or mild disease showed the limitations of the unaided senses. It became necessary to turn to instruments or procedures that would reveal changes within the body or extend vision beyond the limits of the unaided eye. The x-rays, the Wassermann reaction, chemical methods for blood, urine and tissue and the microscope for examination of blood, urine and tissue have added greatly to the physician's skill in earlier detection and diagnosis. Similarly, long ago the pathologist, recognizing that much was occurring below the threshold of his vision, turned to the microscope to open the realm of cellular pathology.

So it has been with the detection of deficiency diseases. The early and mild states are below the manifest level. The pathogenesis of deficiency diseases makes the existence of these states thoroughly understandable. Among the manifestations of a deficiency disease on a dietary basis are lowered concentrations of the essential factor in the blood, depleted storage in the body's reservoirs, diminished excretion, microscopic change in the tissue in the initial site, gross morphologic and functional change. These manifestations, it should be stated, are not necessarily or ordinarily concurrent. To detect these states below the manifest level, investigators have had recourse to new procedures and instruments. For most deficiency diseases these states have been demonstrated by appropriate methodology. Hess's⁵⁰ visualization of a state characterized by a negative balance in the vitamin has been confirmed by biochemical methods in analyses of blood and urine. Indeed, low blood values for ascorbic acid have been found in a definite proportion of population samples.⁵¹ True, some investigators have argued that such values for ascorbic acid in the absence of other signs do not constitute scurvy. Judged by clinical criteria, the condition is not scurvy. Not until it has advanced to macroscopic tissue changes and developed signs is it designated scurvy. But that view draws a purely arbitrary distinction. Its justification is that it differentiates two states of severity in the process. One is the lesser developed state, the other the fully developed disease. But whatever the former is called, it is a step in the process. As a practical matter it may call for treatment.

Several procedures have been employed to elicit or detect the so-called monosymptomatic state before the sign has become manifest. It is obvious that the value of this approach for recognition of the incipient deficiency disease depends on testing or examining for the earliest sign. Instruments and methods have been devised for the detection of night blindness⁵² and capillary fragility,⁵³ as evidence of avitaminoses A and C respectively. These conditions occur, but they are not

monosymptomatic, for it has been shown that they are not the earliest signs of these avitaminoses.⁵³

More illuminating on the existence of the early state in a deficiency disease has been the observation of morphologic changes imperceptible to the unaided eye. Beginning changes in bones in infantile scurvy revealed by x-ray examination have been described.⁵⁴ Biomicroscopy, however, has disclosed still more about the early state of several deficiency diseases. Just as the microscope was highly useful to the pathologist in extending his range of vision to lesser changes in post mortem tissue, it has now proved highly informative to apply it in deficiency diseases to changes in living tissues. It is particularly revealing when the tissue site among the first showing changes is selected for observation. Using this procedure, I have found early specific biomicroscopic changes in four deficiency diseases in the conjunctiva in avitaminosis A,⁵⁵ in the cornea in ariboflavinosis,⁵⁶ in the tongue in aniacinosis⁵⁷ and in the gum in avitaminosis C.⁵⁸

Thus, alteration in transport and storage and microscopic changes in tissue show that deficiency diseases do exist in an early state which is undetectable by ordinary clinical methods.

In this morphologic study of these deficiency diseases, with biomicroscopic in conjunction with macroscopic examination, it was possible to see all gradations and to reconstruct the sequence of changes. These observations combined with the results from administration of specific therapy, revealed new states. Besides the severe and early acute forms, I noted chronic states of varying intensity from mild to severe. These chronic states took on immediate significance because of their predominance in the population.

While each of the four deficiency diseases avitaminosis A, ariboflavinosis, aniacinosis and avitaminosis C has its individuality as a separate and specific entity, all in the evolution and recession of their particular lesions showed a similarity in their biologic behavior. They reflected a definite biologic pattern. From this was elaborated a concept of deficiency states, their nature, their evolution how they may be recognized and their response to specific therapy.⁶⁰

According to this concept, the specific pathologic process in a tissue in a deficiency disease⁶⁰ is characterized by velocity, intensity and duration. Of the velocities occurring, the range may be classified arbi-

60 To many persons the term "deficiency disease" connotes a disorder arising solely from a deficiency in the diet. True, dietary inadequacy is the most common cause but there are many other causes and condition ing factors. They are discussed in a separate article in this series by Dr. Norman Jolliffe. As the result of any of these causes and conditions tissues are deficient in or cannot use the essential. It is desirable that the term deficiency carry this broader meaning.

trarily and most simply into two principal categories which are subdivided. The acute process is rapid in appearing, in running its course and in receding under treatment. Somewhat less rapid is the subacute or mild acute process. Differing from these in velocity, the chronic process is slow in onset, progress and response to treatment. Even slower is the mild chronic process.

Since the pathologic process may be of any intensity, it is convenient to graduate arbitrarily the range in two degrees, mild and severe. Therefore the acute and the chronic process may be either mild or severe. With grouping by form and intensity, the simplest classification of processes provides the categories mild acute, mild chronic, severe acute and severe chronic. These are the same groups that were enumerated in designating a process according to its velocity.

If uninterrupted, the process manifests its changes in a definite sequence which may be divided into stages. Therefore in each of the categories it may be divided into stages. Naturally the duration of the process will be a factor determining its stage.

(To be continued)

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE

TENTATIVE MINIMUM REQUIREMENTS FOR ACCEPTABLE ELECTRICAL HEARING AIDS WERE PUBLISHED IN THE JOURNAL MAY 11 1940. THESE REQUIREMENTS ARE REVISED FROM TIME TO TIME AS THE RESULT OF THE IMPROVEMENTS AND CHANGES MADE IN THE INSTRUMENTS. THE COUNCIL ON PHYSICAL THERAPY WISHES TO EXPRESS ITS APPRECIATION FOR THE VALUABLE ASSISTANCE RENDERED IN THE PREPARATION OF THIS REPORT BY THE CONSULTANTS ON AUDIOMETERS AND HEARING AIDS. THE CONSULTANTS ARE DR. W. E. GROVE, CHAIRMAN, AND DRS. GEORGE M. COATES, EDWIN P. FOWLER, WALTER HUGHSON, ISAAC H. JONES, DEAN V. LIERLE, DOUGLAS MACFARLAN, C. STEWART NASH, HORACE NEWHART, PAUL E. SABINE AND BURT R. SHURLY.

HOWARD A. CARTER, Secretary

MINIMUM REQUIREMENTS FOR ACCEPTABLE ELECTRICAL HEARING AIDS

A hearing aid acceptable to the Council on Physical Therapy of the American Medical Association shall improve at least 30 decibels for speech the hearing of the deafened ear for which it is prescribed or fitted. Firms shall meet the following requirements:

1. Hearing aids shall have imprinted on each transmitter and air or bone conduction receiver a model number (type or class) or some equally suitable identification.

2. The manufacturer shall supply the Council on Physical Therapy with a graph giving the amount of amplification.

3. The manufacturer shall state the voltage and current consumption at maximum setting.

4. The hearing aid shall be free from unwarranted noises such as sizzling, frying, humming, clicking and whistling sounds.

5. The manufacturer shall furnish to the Council a copy of its guaranty to the purchaser.

6. There shall accompany each hearing aid clearly written instructions for its use.

7. The manufacturer shall give evidence that adequate facilities for servicing the instruments are available and shall furnish names and addresses of servicing agencies.

8. The manufacturer shall agree to furnish from stock to the Secretary of the Council on Physical Therapy a hearing aid for inspection and test. On the request of the Secretary, the manufacturer shall supply him with an order on any of the authorized agents for an instrument for test. On the completion of tests the instrument shall be returned complete to the manufacturer.

9. All material used in manufacture shall be of first grade and the workmanship skilfully performed.

10. The firm shall be responsible for the ethical merchandising practices, financial dealing and contracts of its agents, sales representatives and service men with the purchasers of the instruments. The standards of merchandising and the acceptability of advertising shall meet the Rules of the Council on Physical Therapy.

REPORT OF THE COUNCIL

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER, Secretary

McINTOSH SINUSTAT ACCEPTABLE

Manufacturer: McIntosh Electrical Corporation, 225-227 North California Avenue, Chicago.

The McIntosh #1518 Sinustat is said by the manufacturer to provide a simple means of obtaining various forms of sinusoidal and galvanic wave currents capable of producing rhythmic contractions of muscular tissue both striated and unstriated at frequencies corresponding to the norm of each. The unit is encased in a walnut cabinet measuring 20 inches by 13 3/4 inches by 12 1/2 inches and weighing 49 pounds. It is designed for operation on 100-115 volts, 60 cycle alternating current. Standard accessories include treatment cords, metal treatment handles, interrupting treatment handle with spongio disk, 4 by 6 "kautern" pads and rubber bandages.

On the control panel of the unit are located a push button switch for selecting the kind of current, a meter recording patient current intensity, a red light and a green light indicating sinusoidal and galvanic currents respectively, two rheostats, one controlling the patient circuit and the other the speed of waves, a line switch and a polarity switch. A transformer, a heavy duty motor, a full wave rectifier tube, a condenser and a variable speed motor are mounted on the chassis.

The report of the Council's investigation of the apparatus is as follows:

McIntosh Sinustat

The McIntosh #1518 Sinustat is a generator designed primarily for electrical muscle stimulation. It has six current forms as follows:

1. A direct current which is designated as a straight galvanic current. This is an essential current for muscle stimulation using the make and break technique for ion transfer and other direct current applications.

2. A surging interrupted direct current, which is designated as galvanic unidirectional current. This current can be used for the electrical stimulation of muscles with an intact nerve supply and where, in addition, the polar effects of the direct current are desired.

3. A surging uninterrupted direct current with alternate polarity which is designated as a galvanic smooth, the form of this current, according to the name plate, is sinusoidal in form. This current is effective in the stimulation of paralyzed muscles, that is, muscles exhibiting the reaction of degeneration. This current was tested on patients and experimental animals.

4. A surging interrupted direct current with alternate polarity, which is designated as galvanic rough. It is similar in form to 3, only interrupted. This is effective for the electrical stimulation of skeletal muscles with an intact nerve supply.

5. A tetanizing current, which is designated as a 320 sinusoidal current. This produces a sustained tetanic contraction of the skeletal muscle with an intact nerve supply. This current produces similar effects to any faradic current. This current could be used for the so-called "muscle faradization."

6. A surging 320 cycle alternating current, which is designated as a 320 sinusoidal wave. Evidence is not available that this current is useful; in fact, the Council's experimental work tends to show that this type of current may produce harmful effects.

CONCLUSIONS

Current 1 is an essential current

Current 2 can be used for the stimulation of a muscle with nerve supply intact and when at the same time constant polar effects are desired. It is not essential but can be used.

Current 3 is an essential current for the treatment of muscle giving the reaction of degeneration.

Current 4 is an essential current for the stimulation of a muscle when the nerve supply is intact.

Current 5 is not an essential current, although it will produce complete tetanus of a muscle. It can be used when a complete sustained tetanic contraction may seem desirable.

Current 6 is a current for which there is no definite evidence of usefulness or harmlessness.

The Council voted to accept the McIntosh #1518 Stimulator for inclusion on its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
AUSTIN E. SMITH, M.D., Secretary

ZINC INSULIN CRYSTALS

and

CRYSTALLINE ZINC INSULIN INJECTION

Because of difficulty in arriving at a name which would accurately describe this insulin preparation and be approved by the Insulin Committee of Toronto, the Council has held in abeyance any report on this subject although the subject has been under consideration since the introduction of these agents into the medical armamentarium. Because of its responsibility to the public and to the physician the Council was of the opinion that it should not delay issuance of an explanation concerning the status of zinc insulin crystals but a desire to obtain complete cooperation from all interested bodies motivated a delay. However, the patents for insulin have expired and standards have now been set up by the United States Pharmacopeia for enforcement by the Food and Drug Administration.

Three forms, (1) solution of an amorphous form of insulin, (2) solution of protamine zinc insulin and (3) solution of zinc insulin crystals, are now available commercially and have been accepted for inclusion in New and Nonofficial Remedies. There have been two current designations for preparations of zinc insulin crystals, in the United States it was marketed as "Insulin specially prepared as Solution of Zinc Insulin Crystals" and in Canada as "Insulin made from Zinc Insulin Crystals." As the Council on Pharmacy and Chemistry was of the opinion that differentiation between "amorphous" and "crystalline" insulin was not made sufficiently clear by these designations considerable correspondence was conducted with the Committee Advisory to the Insulin Committee of Toronto with a view to adoption of a name more accurately descriptive of the preparation. Finally, the designation "Solution of Zinc Insulin Crystals—a specially purified preparation of Insulin" was evolved and appeared to be satisfactory to both the Council and the Committee Advisory. This term was to encompass the product originally described as "Insulin, specially prepared in the form of zinc insulin crystals."

Just as it appeared that the status of the problem was ready for publication, correspondence arrived at the Council office indicating that the discussion was again to be opened. The arguments for this were not convincing to the Council, and it therefore held to its decision regarding the acceptance of the designation "Solution of Zinc Insulin Crystals—a specially purified preparation of Insulin," and voted to accept Zinc Insulin Crystals and Solution of Zinc Insulin Crystals—a specially purified preparation of Insulin, for inclusion in New and Nonofficial Remedies.

However, the U S P Revision Committee adopted the following designations for insulin preparations, although at present the U S P XII contains a monograph only on Insulin Injection.

Injectio Insulini (Insulin Injection)

Injectio Zinci-Insulini Crystallini (Crystalline Zinc Insulin Injection)

Injectio Zinci-Insulini Protaminæ (Protamine Zinc Insulin Injection)

As a result of its consideration of commercially available insulin solutions made from zinc-insulin crystals, the Council concluded that clinically it is impossible to differentiate between Insulin Injection U S P prepared from zinc insulin crystals and that prepared from amorphous insulin, and that under the provisions of the federal Food, Drug and Cosmetic Act a manufacturer could prepare a solution of zinc insulin crystals and, without any statement as to its source, label and market it simply as Insulin Injection. Thus no label distinction between ordinary insulin solution and solution zinc insulin crystals is required.

After reviewing the findings, the Council voted to publish immediately the foregoing statement and to accept for inclusion in New and Nonofficial Remedies, Zinc-Insulin Crystals and Crystalline Zinc-Insulin Injection.

ZINC INSULIN CRYSTALS—Zinc insulin crystals occur as a crystalline preparation of the active antidiabetic principle of the internal secretion of the islands of Langerhans of the pancreas. The crystals contain a small amount of zinc (not less than 0.45 per cent and not more than 0.9 per cent), which is chemically combined with the active principle. The presence of zinc or some other heavy metal such as nickel or cobalt is essential because only in the presence of traces of such elements has the active antidiabetic principle been prepared in a pure crystalline form. Each milligram of the crystals is equivalent to approximately 22 units of insulin. The product is marketed in the form of crystalline zinc-insulin injection.

Zinc insulin crystals occur as small colorless rounded untwinned uniaxial rhombohedral crystals possessing a negative optic sign parallel or zero extinction between crossed Nicols and a mean index of refraction for lithium light of 1.535 ± 0.002 with a birefringence of 0.005. It is sparingly soluble in water, insoluble in alcohol, chloroform and ether but soluble in dilute acid and dilute alkali. The isoelectric point of zinc insulin crystals is about 5.3. The crystals are stable if kept at a low temperature.

Transfer to a microscope slide approximately 0.1 mg of zinc insulin crystals and 0.1 cc of distilled water, thoroughly wet the crystals by stirring with a small glass rod, the crystals do not dissolve completely but give rise to a turbid suspension, under microscopic examination the crystals conform to the petrographic description of zinc insulin crystals. The crystals brown rapidly when heated above 220°C and melt with decomposition between 230 and 240°C.

Transfer about 20 mg of zinc insulin crystals to a platinum boat weigh the boat and its contents within a weighing pig, place the boat in a vacuum desiccator over phosphorus pentoxide and dry to constant weight using the weighing pig, to prevent the absorption of water during weighing. The loss in weight does not exceed 7.0 per cent. In the following quantitative determinations it is more convenient to weigh the zinc insulin crystals directly and to calculate the results to a dry basis rather than attempt to weigh the extremely hygroscopic dry material.

Dissolve 50 mg of zinc insulin crystals in 5 cc of water by the addition of sufficient tenth normal hydrochloric acid to effect solution transfer to a centrifuge tube and add 2 cc of 10 per cent trichloroacetic acid with shaking let stand ten minutes and centrifuge decant into a 10 cc volumetric flask add 2 cc of Nessler's reagent and make up to volume allow to stand five minutes transfer to a colorimeter and compare with a standard made up similarly and containing 0.055 mg of ammonium sulfate the color does not exceed that of the standard solution.

Transfer 18 mg of zinc insulin crystals to a 100 cc volumetric flask add 2 cc of tenth normal hydrochloric acid dilute to the mark with distilled water and shake to dissolve the crystals. Transfer 10.0 cc of this solution to a separator, add about 20 cc water 10 cc chloroform and 2 cc dithion reagent (prepared by dissolving 15 mg dithion in 100 cc redistilled chloroform). Make the solution alkaline by the addition of ammonia water and shake until the chloroform layer is colored a clear pink. Drain the chloroform layer into a clean flask and repeatedly extract the aqueous layer with small portions of chloroform to which has been added a few drops of dithion reagent until the chloroform is no longer colored pink. At this point the aqueous layer may be discarded. Transfer the combined chloroform extracts to a clean separator and extract twice with 15 cc portions of 0.02 normal ammonia water to remove the excess dithion. After each extraction wash the water layer with a small quantity of fresh chloroform and then add to the main chloroform extract. Dry the combined chloroform extracts with a small quantity of anhydrous reagent quality sodium sulfate decant the solution into a 50 cc volumetric flask, rinse the sodium sulfate several times with fresh chloroform and make the solution to volume with chloroform. Compare the solution in a colorimeter with a standard made as described above using 10.0 cc of a solution containing 0.001 mg zinc per cubic centimeter (3.357 mg zinc acetate $[Zn(C_2H_3O_2)_2 \cdot 2H_2O]$ per liter). The zinc content is not less than 0.45 per cent nor more than 0.9 per cent.

Transfer about 10 mg of zinc insulin crystals to a platinum dish add two drops of concentrated sulfuric acid ash slowly and ignite to constant weight at 600°C. The ash is not more than 50 per cent more than the zinc sulfate calculated from the zinc content and in no case is it more than 3.30 per cent.

CRYSTALLINE ZINC INSULIN INJECTION—A solution of zinc insulin crystals, a preparation containing the active antidiabetic principle of the pancreas, combined with a small amount of zinc (not less than 0.2 and not more than 0.40 mg per thousand units of active principle in the solution)

Actions and Uses—Crystalline zinc insulin injection may be used in the treatment of diabetes mellitus when regulation of diet has been unsatisfactory in control of the disease. Because of its chemical purity, solution of zinc insulin crystals is especially indicated for patients who may be expected to exhibit allergic reactions to insulin. Experience has indicated that the occurrence of such reactions may thus be avoided or minimized. Although early clinical observations indicated that the action of crystalline zinc insulin injection as compared with that of insulin may be slightly delayed and somewhat prolonged, further clinical experience has shown however, that in patients under careful observation crystalline zinc insulin injection and insulin may be used interchangeably.

Dosage—The potency of crystalline zinc insulin injection is measured in terms of standard units of insulin. The general principles underlying its administration are the same as those covering the use of insulin, and under ordinary circumstances the two solutions may be regarded as interchangeable. The crystalline zinc insulin injection is usually best administered subcutaneously fifteen to thirty minutes before a meal. The time and number of the doses and the amount of solution must be determined by the need of the individual patient, each of whom requires accurate dietary regulation and meticulous clinical study.

Marketed solutions of zinc insulin crystals are water clear and contain from 1.4 to 1.8 per cent w/v of glycerin for isotonicity, 0.1 to 0.25 per cent v/v of phenol or tricresol as a preservative and sufficient 0.01 normal hydrochloric acid to yield a pH of from 2.5 to 3.5. The biologic activity of the solution is expressed in U S P insulin units per cubic centimeter. Solutions of zinc insulin crystals are stable, provided the storage temperature does not exceed room temperature. Crystalline zinc insulin injection meets the requirements for identity and purity provided in the U S P XII under *Injectio Insulini*.

CRITERIA FOR EVALUATION OF SKIN DISINFECTANTS

Examination of the literature on skin disinfectants and of the data submitted to the Council in support of such preparations betrays the lack of adequate guiding criteria for the evaluation of surface disinfectants. To aid in clarifying the situation, the Council has declared the advisability of data such as the following in support of any skin disinfectant submitted to the Council for consideration:

1 Phenol coefficients or other *in vitro* tests in the absence and in the presence of serum using both vegetative bacterial cells and clostridial spores, with suitable recovery mediums containing, if known, neutralizing substances for the disinfectant being tested.

2 Data on germicidal efficiency under conditions simulating actual use by the method of Price (Price, P. B. *The Bacteriology of Normal Skin. A New Quantitative Test Applied to a Study of the Bacterial Flora and the Disinfectant Action of Mechanical Cleaning*. *J Infect Dis* 63:301 [Nov-Dec] 1938; *Ethyl Alcohol as a Germicide*. *Arch Surg* 38:528 [March] 1939) or better still by an extension of the method of Price (Beinstein, L. H. T. *Standardization of Skin Disinfectants*. *J Bacteriol* 43:50 [Jan] 1942). The complications due to possible effects of the germicide on the skin itself should be taken into consideration (Cromwell, H. W. and Leflier, Ruth. *Evaluation of 'Skin Degerming' Agents by a Modification of the Price Method*. *ibid*, p. 51).

3 Data on germicidal efficiency by an animal method such for example as suggested by Alice H. Kempf and W. J. Nungester (*An In Vivo Test for the Evaluation of Skin Disinfectants*, *ibid*, p. 49) or R. W. Sarber (*ibid*, p. 50).

4 Evidence from animal experiments regarding irritant action on skin and mucosae and regarding systemic toxicity.

5 Critical clinical evidence supporting claims of harmlessness and efficacy.

6 Data on the bacteriostatic activity as distinguished from the germicidal activity of the disinfectant.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary

DEXTROSE (See New and Nonofficial Remedies, 1942, p. 418)

The following dosage form has been accepted:

READYFLASK, INC., LAKEWOOD, OHIO

Dextrose 5% (W/V) in Isotonic Solution of Sodium Chloride 1,000 cc. Each 100 cc contains 5 Gm of dextrose and 0.85 Gm of sodium chloride—U S P

ISOTONIC SOLUTION OF SODIUM CHLORIDE (See New and Nonofficial Remedies, 1942, p. 425)

The following dosage form has been accepted:

READYFLASK, INC., LAKEWOOD, OHIO

Isotonic Solution of Sodium Chloride 1,000 cc. Each 100 cc contains 0.85 of sodium chloride—U S P in distilled water

QUININE DIHYDROCHLORIDE (See New and Nonofficial Remedies, 1942, p. 217)

The following dosage forms have been accepted:

ENDO PRODUCTS, INC., RICHMOND HILL, N. Y.

Ampuls Solution Quinine Dihydrochloride 0.25 Gm (3¾ grains) in 1 cc. 0.5 Gm (7½ grains) in 1 cc. 1.0 Gm (15½ grains) in 2 cc. Each ampul contains the stated amount of quinine dihydrochloride dissolved in distilled water.

TETANUS TOXOID, ALUM PRECIPITATED (See New and Nonofficial Remedies, 1942, p. 516)

The following dosage form has been accepted:

PITMAN-MOORE CO., INDIANAPOLIS

Tetanus Toxoid (Alum Precipitated) 1 cc vials in packages of two 1 cc vials (two immunizing doses) and 10 cc vial (ten immunizing doses)

PURIFIED SOLUTION OF LIVER (See New and Nonofficial Remedies, 1942, p. 368)

The following dosage forms have been accepted:

JOHN W. WETH & BROTHER, INC., PHILADELPHIA

Purified Solution of Liver, 5 U S P injectable units per cc. 10 cc rubber stoppered ampoule. A sterile aqueous solution of liver preserved with 0.5 per cent phenol.

Purified Solution of Liver, 10 U S P injectable units per cc. 10 cc rubber stoppered ampoule. A sterile aqueous solution of liver preserved with 0.5 per cent phenol.

ETHYL AMINOBENZOATE (See New and Nonofficial Remedies, 1942, p. 65)

The following dosage form has been accepted:

WINTHROP CHEMICAL CO., INC., NEW YORK

Anaesthesin Jelly 1½ oz collapsible tube

PENTOTHAL SODIUM (See New and Nonofficial Remedies, 1942, p. 463)

The following dosage form has been accepted:

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Ampoules Pentothal Sodium 50 Gm with 0.3 Gm anhydrous sodium carbonate as a buffer. Multiple dose ampul

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1942, p. 555)

The following dosage form has been accepted:

LAKEVIEW LABORATORIES, INC., MILWAUKEE

Solution Thiamine Hydrochloride, 100 mg per cc. 15 cc vial. Preserved with 0.5 per cent of chlorobutanol.

PYRIDOXINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1942, p. 563)

The following dosage forms have been accepted:

THE LAKEVIEW LABORATORIES, INC., MILWAUKEE

Ampuls Pyridoxine Hydrochloride, 50 mg per cc. 1 cc

Pyridoxine Hydrochloride, 50 mg per cc. 5 cc vial

Tablets Pyridoxine Hydrochloride 5 mg

ANTIBODY FUNCTION OF LYMPH NODES

For fifty years it has seemed logical to immunologists to assume that specific antibodies are formed as internal secretions by certain fixed tissues. Attempts to determine the essential immunologic endocrines, however, were unsuccessful. Hektoen and his co-workers¹ found that removal of the stomach, small intestine, pancreas, thyroid, spleen and other organs whose surgical removal is compatible with life does not materially reduce the power of the remaining tissues to produce specific opsonins and agglutinins. From this failure they concluded that the antibody producing tissues must be widely distributed throughout all organs, and they directed attention particularly to the capillary endothelium as the most probable tissue. Support was given to this theory by physical or chemical reticuloendothelial blockade, both stimulation of specific precipitin production² and almost complete suppression of production³ being reported as a result of minimal or maximal blockade with such agents as india ink, carmine particles or colloidal dyes. The alleged production of specific hemolysins in certain reticuloendothelial tissue cultures⁴ and their reduced production in animals in which the reticuloendothelial system has been greatly reduced in volume by exposure to x-rays⁵ support this conclusion.

As early as 1898, however, Pfeiffer⁶ had directed attention to lymphatic tissues as the probable source of antibodies. He titrated the bacteriolysins in various organs of rabbits previously injected intravenously with nonviable bacterial vaccines and at times found these antibodies in higher concentration in the spleen than in the blood stream. This, however, was not generally considered proof of local specific antibody formation,

since similar splenic concentrations were noted in rabbits passively immunized by serum transfer. McMaster and others,⁷ however, have recently strengthened the evidence, having shown that in mice local histologic reactions in regional lymph glands are associated with a definite increase in local specific agglutinins, the local titer at times reacting two to four times that of the blood serum.

A crucial test of the lymph gland theory of specific antibody production has now been reported by Ehrlich and Harris⁸ of the department of pathology of the University of Pennsylvania School of Medicine. The Pennsylvania pathologists selected the popliteal lymph node of rabbits as offering a unique opportunity for such study. This gland is the only lymph node draining the hind foot and is supplied with afferent and efferent lymphatics of sufficient size for convenient aspiration. With a tuberculin syringe they could readily collect from 0.2 to 0.6 cc. of lymph from each vessel, amounts sufficient for antibody titration. Ehrlich and Harris therefore injected suspensions of formed antigens, such as heat killed bacilli or washed erythrocytes, into the plantar surface of the left hind foot. At various intervals after this injection they aspirated lymph from both the afferent and efferent lymphatics of the left popliteal gland, with simultaneous titrations of the blood serum, of aqueous extracts of the popliteal gland and of subcutaneous tissues of the injected hind foot. Controls were run with homologous products from the opposite or noninjected leg, or from control leg tissues injected with a heterologous antigen (e.g., egg white).

In all cases the agglutinin or hemolysin titer was higher in the efferent than in the afferent lymph of the injected popliteal gland. Difference was not noted between the afferent and efferent lymph of the control noninjected popliteal space. After passage through the vaccinated lymph node the antibody titer was often increased as much as a hundredfold to a titer often exceeding that of the blood serum. Extracts of the injected foot tissues usually showed titers as low as the titer of the afferent popliteal lymph. The titer of popliteal node extracts was often from two to ten times higher than that of the blood serum, the control popliteal gland showing only traces of specific antibodies.

From this and other evidence Ehrlich and Harris conclude that both hemolysins and agglutinins are formed within regional lymph nodes. They found that antibodies began to appear in the regional nodes from two to four days after plantar injection and reached their highest concentration by the sixth day. Local antibody formation was preceded and accompanied by local

hyperplasia. The local tissue proliferation was chiefly of the lymphatic type, from which they concluded that the lymphocytes are the major (or perhaps the only) local cells responsible for antibody synthesis.

CALIFORNIA PHYSICIANS' SERVICE AND HENRY KAISER'S PERMANENTE FOUNDATION

The hearings before the Pepper subcommittee reported in THE JOURNAL have made physicians familiar with the problems related to the provision of medical service created when Mr. Henry Kaiser undertook to provide for the employees of his various interests in California, Oregon and Washington. The January issue of *California and Western Medicine* publishes some information as to the present status of this situation in California. There are about 87,000 employees in the Richmond yards. The plan in operation provides for a 50 cent weekly payroll deduction for the provision of complete medical care and hospitalization to Kaiser employees who are injured or who may be taken ill from nonindustrial causes. The plan now covers 52,000 employees who have consented to the deduction. To these employees are available the facilities of the Maritime Commission's field hospital and six first aid stations, also the services of a staff of some fifty physicians and a 78 bed hospital in Oakland. This hospital was an old hospital named the Fabiola Hospital, which was purchased, rebuilt and renovated with the sum of \$500,000 loaned by Mr. and Mrs. Henry Kaiser under the name of the Permanente Foundation. An additional wing of 75 beds is being added to the original 78 beds.

The income of the plan, it is reported, is designed to meet current expenses and to amortize the loan of \$500,000 from Mr. and Mrs. Kaiser. Several commercial insurance carriers handle industrial accident liabilities in the plant. The industrial medical fees paid by the insurance companies also accrue to the foundation. The Permanente Foundation is a nonprofit venture. When the \$500,000 advanced by Mr. and Mrs. Kaiser has been repaid in full, further profits are to be used for the promotion of medical research, for the rehabilitation of disabled physicians, for the endowment of hospital beds and for the teaching of industrial medicine. The plan is administered by Dr. Sidney R. Garfield under an agreement which allows him to draw up to \$25,000 annually in salary. A statement by Dr. Garfield, according to *California and Western Medicine*, indicates that thus far he has not drawn any salary from the funds of the foundation but has, in fact put into current operating funds some \$10,500 of his own money, with the understanding that this also is to be repaid from the funds that accrue in the future. The statement in *California and Western Medicine* indi-

cates that the facilities and the quality of the medical service provided are excellent.

One of the chief questions raised before the Pepper hearings concerned the relationships of the Procurement and Assignment Service to the medical care plan of Mr. Kaiser. On this subject *California and Western Medicine* says:

Early in its existence in California Procurement and Assignment Service became aware of the building up by Mr. Kaiser and Dr. Garfield of a staff of physicians for both the industrial and nonindustrial medical care of Kaiser employees. The Kaiser staff of some thirty physicians (early in 1942) represented a group of young men, all but two of whom were definitely of military age.

A review of the Kaiser medical staff showed that practically every one of the thirty physicians should be declared available for military service because of his age, at the same time Procurement and Assignment Service had no intention or desire to break up an established staff which was caring for an important segment of the industrial population.

Complaints had been heard from the medical profession that the Kaiser staff was practicing "corporate medicine," that Dr. Garfield had resorted to "piracy" in hiring his physicians; that the whole operation was an unethical one that doctors eligible for military service were being offered sanctuary and protection from Selective Service. Procurement and Assignment Service took the attitude, however, that its function had nothing to do with ethics and that its approach to the problem must be from the point of view of the distribution of physicians between military and civilian agencies.

At the same time, Procurement and Assignment Service put Dr. Garfield on notice that his staff members were vulnerable to induction into the Army by Selective Service because of their low average age. This warning was given for the protection of the staff, to obviate the disruption that might occur if a large part of the staff was classified I-A by local draft boards and forced into military service.

On the basis of the above reasoning a program was worked out whereby Dr. Garfield would clear through Procurement and Assignment Service any physicians who were under consideration for employment on his staff. It was understood that those physicians who otherwise would be available for military service were not to be employed by Dr. Garfield except for a temporary period, while they awaited the issuance of their commissions and orders for active duty.

A second part of this program called for the replacement of any four young staff members every ninety days, replacements were to be by physicians over military age or physically disqualified and rejected for military service. Procurement and Assignment Service agreed under this program to declare "essential" the remaining members of the Garfield staff until the time for replacement of each staff member should come up.

This program was put into operation. Procurement and Assignment Service has referred to Dr. Garfield no less than twenty-five physicians who are either too old for military service or have been rejected by the Army. Some of these have been acceptable to Dr. Garfield and have been employed by him; some have been unable to perform the medical duties with satisfaction. Nine of the former members of the Garfield staff have been accepted for military duty and have been replaced by other physicians. The program is somewhat behind schedule at present because Dr. Garfield found it necessary shortly after the start of the program to increase his staff to care for the increasing number of employees who have signed up for the plan and to cover the expanding program of the shipyard.

The California Physicians' Service, a nonprofit medical care organization sponsored by the California Medical Association, has also undertaken the health care of wartime industrial employees in shipyards and

other areas on an area basis. Outside the industrial plants its services are provided to employees and their families who reside in Federal Housing Authority projects which have been built around the industrial plants. The California Physicians' Service operates a medical center in each of the housing areas that it serves. The staff physicians and nurses in the medical centers give immediate care to the industrial employees and their families and refer to members of the California Physicians' Service in the immediate vicinity cases which require hospitalization, surgery or more extensive medical care. The Federal Public Housing Authority adds the monthly charge for California Physicians' Service to the rental of the housing unit and turns the collections over to the California Physicians' Service. Under this arrangement any profit that may accrue must be returned to the subscribing employees and their families in the form of either reduced fees or increased services. The cost of hospitalization is included in the California Physicians' Service fee.

Among questions not yet determined are (1) the extent to which the Permanente Foundation plan will be expanded to care for families of employees, (2) whether or not the Garfield plan will be expanded to include care of employees living outside the service area of the hospital in Oakland, one San Francisco physician has already been employed to make house calls, (3) the extent to which the Permanente Foundation and the California Physicians' Service may work out a cooperative plan, (4) the financial arrangements involved when an employee finds that by living in a Federal Housing Authority housing project he is entitled to medical care both from the Permanente Foundation and from the California Physicians' Service plan.

Readers of THE JOURNAL will remember that physicians in Oregon worked out arrangements satisfactorily for the Kaiser employees near Portland. It should be remembered, however, that the chief question at issue in the Pepper hearings was the utilization of medical manpower and the desire of the Kaiser organization to retain the young physicians in its hospitals whereas the Procurement and Assignment Service had designated them as eligible for service with the armed forces. It will be observed that nine of these physicians are now with the armed forces. The alleged opposition of the medical societies of the states concerned to prepayment plans for medical service seems to have been introduced into the discussion for the one purpose of prejudicing public opinion on the other issue. The manner in which California Physicians' Service has been cooperating with other agencies in supplying medical care in the emergency that prevails is in itself proof of the lack of validity associated with introducing that point in the hearings.

FIBRINOGEN EMBOLI FROM SUPERFICIAL BURNS

A timely addition to our knowledge of the pathology of superficial burns has been made in a study of the toxicity of heated human plasma recently reported by Kabat and Levine¹ of the Department of Physiology, University of Minnesota. In the course of extensive experiments on thermal shock in anesthetized cats it was noted that a small proportion of the animals succumbed within a few minutes after burning. The respiration stopped suddenly, the heart beat was slow and irregular and the blood pressure fell precipitously. Artificial respiration usually did not result in recovery. Hemocoagulation was minimal at the time of death. Since the sudden death could not be explained on the basis of fluid loss and since nervous factors had been experimentally eliminated the phenomenon was attributed to a toxin.

Measurements of subcutaneous temperatures in experimental scalds showed that temperatures of 55 to 65 C are reached and maintained for several minutes. Citrated cat blood was therefore heated to 65 C for one minute and from 3 to 4 cc of this heated blood injected intravenously into the same animal. The respiration ceased within two minutes. The heart continued to beat for five minutes. Artificial respiration was without avail. Rapid death was also observed following intravenous injection of 2 cc of heated autogenous plasma. Intravenous injection of heated serum even in much larger amounts was without toxic effects. The supernatant of centrifuged heated plasma also was nontoxic. This suggests that the fine precipitate formed in the heated plasma is the toxic agent. The precipitate is presumably partially denatured fibrinogen.

Evidence indicates that the particle size rather than the chemical constitution of this precipitate determines its toxicity, since heated plasma can be rendered innocuous by simple homogenization in an apparatus capable of breaking up tissue cells. As much as 40 cc of homogenized heated plasma can be injected without appreciable toxic reaction. Evidence also indicates that the rate of injection rather than the volume injected determines toxicity. In one experiment for example, 13 cc of heated plasma was injected slowly without producing rapid death. The injected cat survived for four days during which time it was very weak and made almost no spontaneous movements. Necropsy showed a perforating gastric ulcer 1 cm in diameter.

To test possible applications to human medicine a similar study was made of the effects of intravenous injections of heated human plasma into unanesthetized rabbits. Human plasma heated to 56 to 65 C showed the same type of precipitate as that observed with heated cat plasma, while precipitate was not formed in heated human serum. Rapid injection of 2 to 5 cc

¹ Kabat, Herman, and Levine. *Milton Science* 96: 476 (Nov. 20) 1942.

ot heated human plasma into the ear vein of a normal rabbit resulted in prompt respiratory arrest, death taking place in from five to ten minutes. The centrifuged precipitate of the heated plasma gave the same toxic reaction, while the plasma supernate was nontoxic. Also the precipitate in heated human plasma could be rendered nontoxic by homogenization. Here also it is presumably the particle size rather than chemical composition that determines toxicity. Microscopic examination of the lungs of rabbits which died from injection of heated human plasma revealed widespread and numerous capillary protein thrombi.

The possibility that capillary emboli may play an important part in the pathology of severe burns was suggested by earlier investigators. Frankel,² Bardeen³ and others, for example, noted minute capillary thrombi in the liver, spleen and kidneys in cases of burns while Billroth⁴ had previously supported the embolic theory of Curling's ulcer. Salvioh,⁵ Vaccarezza⁶ and others found that canine blood became hypocoagulable following severe burns and that previous defibrination of the blood rendered the dogs more resistant to lethal burns.

Determination of the exact chemical composition of the toxic "fibrinogen precipitate" must precede any attempts at logical therapy.

Current Comment

THE COCOANUT GROVE FIRE

The Coconut Grove night club fire in Boston on Nov. 28, 1942, in these days, each of which brings some new tale of conflict or disaster, now seems like ancient history. Some of the medical aspects of that disaster were discussed in *THE JOURNAL*.¹ A preliminary report by Moulton, technical secretary of the National Fire Protection Association indicates that the lessons of that disaster will not be lost. The onset and course of the fire, the structural features and design of the property, fire fighting operations, activities of emergency organizations and the factors which contributed to the immensity of the disaster are fully described. Most of the victims died from burns and inhalation of smoke and flame. The statement of Dr. Watters, associate medical examiner of the Southern Suffolk District, says he remembered only one broken bone—a rib—in the hundreds of bodies he examined, apparently people died too quickly to fight for their lives. The victims seem to have been overcome by something more than carbon monoxide. The report reviews the different theories which have been proposed to explain the rapid spread of the fire and to account for the fumes described by survivors as acrid but not identified. Fire experience all too clearly shows that the fear of being burned to death or suffocated, the

rush of smoke and hot gases and the sight of spreading flame completely alter the pattern of logical human behavior and produce panic. In this disaster as in others panic unquestionably played a large part in the number of fatalities. The activities of emergency organizations were on the whole satisfactory although they demonstrated one serious fault: there was no apparent central authority in charge at the fire. The club was poorly provided with exits; many exits were completely obscured by false walls, doors were kept locked, revolving doors jammed as usual and behind these two hundred bodies were found even those exits which were available were not all clearly marked. At the close of its term the Grand Jury then in session voted ten criminal indictments with the possibility of more to come. What emerges from this report in particularly bold relief is the ease with which this great loss of life could have been entirely avoided.

NEW OPPORTUNITIES IN HEALTH EDUCATION

Last week an announcement of fellowship made available by the W. K. Kellogg Foundation through the United States Public Health Service for training personnel in health education was published in *THE JOURNAL*, page 525. This training will take place at the University of North Carolina at Chapel Hill beginning March 20, 1943 and be completed in March 1944. This action is based, according to a communication from the United States Public Health Service¹ on the tremendous demand for well qualified health education personnel needed in local and state health departments. This opportunity for training in public health education should be welcomed by interested physicians or educators. The field of health education has long lacked physicians who can teach or teachers with an adequate background of the medical sciences. Out of training such as this teachers with the necessary basic qualifications should be developed. There will be an increased demand for them after the cessation of hostilities not only in the United States but presumably elsewhere. In this connection attention is called to the action of the Trustees of the American Medical Association in providing a short refresher course in health education at the headquarters of the American Medical Association under the direction of the Bureau of Health Education. Qualified applicants may register for two weeks' observation, demonstration and participation in the health education work of the American Medical Association. No tuition or fees are involved but the applicant is expected to defray his own expenses. Full information may be had from the Bureau of Health Education.

1 Letter of Jan. 23, 1943 to Bureau of Health Education from I. R. Coffey, Assistant Surgeon General, Division of Sanitary Reports and Statistics, U. S. Public Health Service.

2 Candidates will present a background of basic cultural education, basic science including physics, chemistry, biology, physiology, and bacteriology, training in education and educational psychology and social science education. The minimum educational qualifications will be a Bachelor of Science degree or its equivalent with major emphasis on basic medical science education or the social sciences. The fellowships are open to American citizens between the age of 19 and 40 inclusive. A stipend of \$100 per month for twelve months plus tuition fees and travel for three months of field experience will be allowed. The applicant however must pay his own travel to and from the university at the beginning and end of training. Application blank may be had from the United States Public Health Service, Security Administration, Washington, D. C.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY

EPIDEMIC KERATOCONJUNCTIVITIS

Circular Letter No. 14 of the Office of the Surgeon General is concerned with the treatment of epidemic keratoconjunctivitis. It was issued on January 11 to all medical officers of the United States Army. The suggestions which follow are therefore recommended as routine in the army medical service.

1 The purpose of this circular letter is to bring to the attention of medical officers an inflammatory disease of the eye which has recently been given the descriptive name of epidemic keratoconjunctivitis. It is called also virus conjunctivitis and keratitis maculosa. The disease resembles superficial punctate keratitis, keratitis nummularis and keratitis subepithelialis. Although this disease is not new, having been reported since 1890 in Austria, Germany, India and the Orient, its recent spread is of importance to the Army and to industrial plants engaged in work for the Army.

2 During the summer of 1941 an outbreak of this acute inflammatory eye disease occurred in the Hawaiian Islands among shipyard workers and subsequently spread to members of the armed forces and civilians in the adjacent areas. A spread to the mainland followed in September 1941, the first cases being noted in shipbuilding plants in the San Francisco region. In October 1941 cases were seen in Oregon again among workers in shipyards. The peak of this West Coast epidemic was reached in January 1942. Recently cases have appeared in epidemic proportions in industrial plants in the Eastern United States.

3 The etiology of epidemic keratoconjunctivitis is unknown, although evidence at present points to a filtrable virus as the causative agent. The disease probably is transmitted to susceptible persons by direct and indirect contact, such as touching the eye with a contaminated hand or towel. The presence in the immediate surroundings of noxious gases, fine particles of metal or dust or other substances irritating to the eyes may enhance susceptibility. The incubation period is from five to twelve days with the onset of the majority of cases on or about the eighth day after exposure. The disease is limited to one eye in about 75 per cent of cases. The involvement of the other eye, when it occurs, is usually less severe.

4 The initial symptoms are those of acute follicular conjunctivitis. In many cases the onset is sudden and severe. The conjunctivitis is characterized by 'sandy feeling,' as if a foreign body were present. Examination of the eye at this time discloses an extremely congested and chemotic conjunctiva, rather glassy in appearance, with sometimes concomitant edema of one or both lids, particularly the upper. Petechial or larger conjunctival hemorrhage may occur. The conjunctivitis persists about two weeks. There is no discharge, although a transient pseudomembrane may appear on the palpebral conjunctivas and caruncle. Systemic symptoms composed of headache and malaise occur shortly after the onset of the conjunctivitis in from 25 to 50 per cent of the cases. The headache, a moderately severe, dull, aching pain over the frontal or occipital region lasts two to three days and is apparently unrelieved by analgesics in most cases. It frequently prevents sleep and is often described as a "night pain." The malaise, when it occurs, varies in intensity with the severity of the conjunctivitis in most instances and is described as "not feeling well" or as having an "achy feeling." A preauricular adenitis appears in about 75 per cent of the cases thirty-six to forty-eight hours after the onset of the conjunctivitis. The nodes usually measure 1 to 2 cm in diameter,

are tender and may remain enlarged from one week to several months. A keratitis appears about one week following the first symptoms of the conjunctivitis. This is characterized by sudden pain, photophobia, lacrimation and blepharospasm. Close inspection of the eye at this time reveals several dotlike opacities in the cornea. These gradually become larger and coalesce to form small round opacities from 0.5 to 1.5 mm in diameter. The symptoms due to the onset of the keratitis usually last about one week but in some cases persist for two to six weeks. With the appearance of the keratitis the visual acuity is definitely diminished. Patients sometimes complain of seeing halos around objects. Precision work at this time is almost always impossible. A 20/30 vision is usually regained in some three to six weeks and the ultimate prognosis as to vision is good. The disease is self limited usually lasting from one to three months but sometimes much longer. The corneal opacities do not ulcerate, gradually diminish in size and in most instances finally disappear. In some severe cases, however, damage to the cornea causes permanent impairment of vision.

5 Ber's acute follicular conjunctivitis, inclusion body conjunctivitis and acute trachoma are among the conditions to be considered in the differential diagnosis. There is no way of differentiating Ber's conjunctivitis with certainty early in the course of the disease, but in Ber's conjunctivitis the cornea is never involved and the preauricular adenitis is not pronounced. The diagnosis of both inclusion body conjunctivitis and trachoma can be established by the demonstration of inclusion bodies in the conjunctival scrapings. The preauricular glands are almost never involved in either, and both respond readily to sulfonamide therapy. In addition, the cornea is not involved in inclusion body conjunctivitis and in trachoma exhibits pannus formation. Other types of conjunctivitis to be considered in the differential diagnosis are acute catarrhal conjunctivitis, gonococcal ophthalmia, Parinaud's conjunctivitis, tularemia, tuberculosis lymphogranuloma and streptococcal membranous conjunctivitis.

6 The treatment of keratoconjunctivitis is wholly palliative. Cold compresses afford more relief than does heat. The eyes should not be bandaged. Protection from the light by smoked or darkly tinted glasses is desirable. There is no specific therapy.

7 The early recognition and prevention of spread of this disease in army posts and stations are particularly important because of its high noneffective rate. Precautionary measures which should be carried out consist in: (1) Isolation of the patient during the acute stage of the disease, if practicable. Patients should have no access to towels, soap or washstands used by others. Where a small number of cases occurs, strict isolation is desirable. (2) Careful supervision of patients with irritated eyes, chazions and traumatic lesions of the eyes which render them more susceptible to keratoconjunctivitis. (3) Advice to the patients that this disease may be transmitted by hands, towels, handkerchiefs and other fomites that have been in contact with the infected eye. (4) Thorough washing of the hands after examination of a suspected patient and before examination of other patients. (5) Sterilization of solutions, eye droppers and instruments used in eye cases. It is particularly important for the responsible medical officer to see that the fourth and fifth precautionary measures just mentioned are observed, since the dispensary can become the focus for the distribution of keratoconjunctivitis to patients who otherwise would not be exposed.

8 It should be noted also that typical cases may be present not only during an epidemic but also during the period preceding an explosive outbreak of the disease. Therefore particular attention should be paid to unusual cases of conjunctivitis that do not fall into any well known categories.

ASHFORD GENERAL HOSPITAL AT WHITE SULPHUR SPRINGS

The War Department on Sept. 29, 1942, acquired the Greenbrier Hotel, White Sulphur Springs, W. Va., and has designated it as the Ashford General Hospital in honor of the late Col. Bailey K. Ashford of the Medical Corps.

The hospital which ultimately will have a 2000 bed capacity, will provide all forms of medical and surgical care. The commanding officer is Col. Clyde M. Beck, Medical Corps, and the executive officer is Lieut. Col. Sam F. Seeley, Medical Corps, who until recently was executive officer of the Procurement and Assignment Service, War Manpower Commission. While still in process of development, the hospital is already caring for several hundred patients. The staff when complete will represent the best in medicine, surgery and the specialties. The members now on duty are as follows:

Lieut. Col. Daniel C. Elkin, M. C., Whitehead professor of surgery and Surgeon in chief, Emory University Hospitals, Atlanta, Ga.

Major James M. Brown, M. C., formerly registrar, Station Hospital, Camp Robinson, Arkansas.

Major Cecil B. Hert, M. C., instructor in otolaryngology, University of Rochester, surgeon to Strong Memorial Hospital, chief bronchoscopist, Rochester General Hospital, Rochester, N. Y.

Major Robert A. Kilduff, M. C., director, Laboratories, Atlantic City Hospital, city bacteriologist, city of Atlantic City, N. J.

Major R. H. Kunstadter, M. C., associate attending pediatrician and chief of Child Endocrine Clinic, Michael Reese Hospital, Chicago.

Major T. W. Maloney, M. C., chief electrocardiographic department, Geneva General Hospital, Geneva, N. Y.

Major John M. Masters, M. C., ophthalmologist, Indiana University Hospitals, Indianapolis.

Major Marsh H. McCall, M. C., clinical instructor in medicine, Cornell University Medical College, associate attending physician, Bellevue Hospital, New York.

Major R. C. Pendergrass, M. C., radiologist, former instructor of radiology, Emory University, director of Americus Tumor Clinic, Atlanta, Ga.

Major John W. Pennock, M. C., associate professor of medicine, Syracuse University Medical School, director, metabolism department, St. Joseph's Hospital, Syracuse, N. Y.

Major George H. Prather, M. C., instructor in genitourinary surgery, Harvard Medical School, visiting urologist, Boston City Hospital, Boston.

Major Barnes Woodhall, M. C., associate professor of surgery, Duke University School of Medicine, Durham, N. C.

Captain M. L. Byrne, M. C., instructor in pathology, University of Louisville Medical School, Louisville, Ky.

Captain Frank L. Bauer, M. C., house officer, Massachusetts General Hospital, fellow Rockefeller Foundation, Boston.

Captain Jack Chesney, M. C., chief, Tennessee Health Department, Pediatric Clinic, Knoxville, attending pediatrician, Knoxville General Hospital, Knoxville, Tenn.

Capt. Lee J. Croll, M. C., associate attending ophthalmologist, Grace Hospital, Detroit.

Captain W. H. Harken, M. C., assistant in surgery, Harvard Medical School, Boston.

Captain M. H. Harris, M. C., Whitehead Fellow in Surgery, Emory University, Atlanta, Ga.

Capt. John H. Iselin, Jr., M. C., assistant attending physician, First Medical Division, Bellevue Hospital, New York.

Capt. Robert P. Kelly, M. C., assistant in orthopedics, Walter Reed Hospital, residents in orthopedics, Louisville City Hospital, Louisville, Ky.

Capt. Samuel B. Kirkwood, M. C., instructor in obstetrics and maternal health, Harvard Medical School, chief of staff, Florence Crittenton Maternity Hospital, Boston.

Capt. Milton L. Kramer, M. C., instructor in Medicine, Cornell University Medical College, associate physician, Beth Israel Hospital and Hospital for Joint Diseases, New York.

Capt. E. N. Pleasants, M. C., chief, Department of Shock Therapy, New Jersey State Hospital, Marlboro, N. J.

1st Lieut. Leonard B. Ainsworth, M. C., surgical staff, Lawrence General Hospital, Lawrence, Mass.

1st Lieut. Russel E. Carlson, M. C., attending surgeon, Lakeview Memorial Hospital, Stillwater, Minn.

1st Lieut. John B. Claffy, M. C., assistant in surgery, Mt. Mericordia and Fitzgerald Mercy Hospitals, Philadelphia.

1st Lieut. Fred Cooper, M. C., instructor in surgery and resident surgeon, Emory University School of Medicine, Atlanta, Ga.

1st Lieut. L. T. Corum, M. C., resident in pediatrics, Grady Hospital, Atlanta, Ga.

1st Lieut. H. L. Dorfmann, M. C., associate physician, Gouverneur Hospital, New York, associate physician, Stuyvesant Polyclinic, clinical assistant, Mount Sinai Hospital.

1st Lieut. William H. Galvin, Jr., M. C., resident anesthesiologist, St. Luke's Hospital, New York, chief anesthesiologist, North County Community Hospital, Glen Cove, L. I.

1st Lieut. John J. McGehee, M. C., surgical staff, Hall Chaudron Hospital, Cedartown, Ga., and McCall Hospital, Rome, Ga.

1st Lieut. Joseph Pott, M. C., instructor in medicine, Columbia University College of Physicians and Surgeons, New York.

1st Lieut. Paul Rieth, M. C., resident in orthopedics, Indiana University School of Medicine, Indianapolis.

1st Lieut. Louis M. Rosati, M. C., clinical assistant in surgery, New York Polyclinic and Gouverneur Hospital, New York.

1st Lieut. Leo M. Traub, M. C., resident in pediatrics, Stanford University Hospital, San Francisco.

1st Lieut. J. L. Weinberger, M. C., staff physician and resident in psychiatry, Worcester State Hospital, Worcester, Ma.

Bailey Kelley Ashford, to whose record of achievement this hospital will be a monument was born in Washington, D. C., Sept. 18, 1873. His father, as professor of surgery in Georgetown University Medical School at the time of the assassination of President Garfield, was among those called in attendance. Bailey Ashford entered the Army Medical Corps in 1897 and joined the expeditionary forces of the army of occupation sent to Puerto Rico in 1898. When Dr. Ashford was stationed at Ponce in 1899 a hurricane wrought such havoc that for nearly a year the care of nearly 800,000 of the native population was assumed by the army. His hospital wards were filled with pallid and emaciated refugees and he promptly recognized the significance of the eosinophilia present. He found a new species of ova in the feces and recognized their relation to the anemia and malnutrition common to the inhabitants of the islands. On Nov. 24, 1899 he reported in a historic telegram his discovery that the cause of 'Porto Rican anemia' was infestation with an intestinal parasite later to be named *Necator americanus*. When the Superior Board of Health in 1900 issued a pamphlet on 'Porto Rican anemia,' the etiologic significance of uncinariasis was recognized as an important medical discovery. In 1904 the Puerto Rican government provided funds for the study and treatment of anemia and authorized the establishment of the Puerto Rican Anemia Commission.

Colonel Ashford early proposed the establishment of a School of Tropical Medicine in Puerto Rico and in 1936 he established the School of Tropical Medicine of the University of Puerto Rico under the auspices of Columbia University in which he served as professor of mycology and tropical medicine.

Colonel Ashford also carried on an investigation of sprue; he was a member of a commission sent to Brazil to investigate an epidemic finally shown to be a combination of malaria and dengue, and in 1910 was a delegate to the International Congress of Industrial Hygiene and Alimentary Hygiene in Brussels. In 1917 he sailed with the First Division for France and later became chief surgeon of the Sixth Army Corps. After the war he was transferred to the general staff in Washington and was made editor in chief of the Official Medical History of the War. Many honors were awarded him: the Distinguished Service Medal, the Order of St. Michael and St. George of England, the Order of the Nile of Egypt, Doctor of Science from the Universities of Georgetown, Columbia, Egypt and Puerto Rico; these were but a few. On Nov. 1, 1934 his distinguished career ended. His body lies in the military cemetery at San Juan. It is fitting that this great hospital at White Sulphur Springs be named after a great and humble man who spent his life in the service of his fellow men.

THE TRAINING OF ARMY LABORATORY OFFICERS

Twenty-four army medical officers, captains and first lieutenants comprise the second group to be assigned to the University of Chicago for intensive training in laboratory methods to equip these officers to take charge of laboratories. The University of Chicago student officers are given forty-four hours of instruction a week for twelve weeks in bacteriology, biochemistry, hematology, parasitology, pathology, serology and tropical medicine. The course is under the direction of Dr. R. Wendell Harrison, assistant dean of the Division of Biological Sciences who is assisted by twelve members of the scientific faculty of the university. Similar work in laboratory methods is given at nine other universities.

LOYOLA HOSPITAL UNIT ON ACTIVE DUTY

About fifty-one members of the faculty of Loyola University School of Medicine, Chicago recently left for New Orleans for several weeks intensive training as members of the staff of U S Army Base Hospital No 108 which is sponsored by the Loyola University School of Medicine and organized under the supervision of Col George T Jordan head of the eye, ear, nose and throat department of the medical school and a veteran of the first world war. Colonel Jordan, who has been in command of the unit for many years has been retired as commanding officer on account of the age limit. The head of the medical section of the 108th Base Hospital is Lieut Col Stanley Fahlstrom and of the surgical section Lieut Col William J Wynalek. The personnel when fully assembled will comprise about 155 doctors and nurses and 500 enlisted men of the medical department. Others who have been assigned to this unit are:

MAJORS
Ellis Bonnell Chicago Ill
Herman F DeLeo Chicago
Angelo S Geraci Chicago
Julius M Glasser Chicago
C H Grundstaff Washington

MAYO CLINIC PROVIDES TRAINING FOR MILITARY OFFICERS

During the current quarter one hundred and forty medical and dental officers of the Army, Navy, Public Health Service and the Air Forces are assigned through the Surgeon General's Offices and the various service commands for training under the auspices of the Mayo Foundation for Medical Education and Research. The fields in which such training is offered are anesthesiology aviation medicine, general surgery and surgical specialties internal medicine and medical specialties maxillo-facial surgery neurologic surgery physical medicine, roentgenology and thoracic surgery. Officers are assigned for periods of training varying from six to twelve weeks.

CIVILIAN DEFENSE

DUTIES OF CITIZENS DEFENSE CORPS IN GAS DEFENSE

A program for civilian protection against gas is being rapidly developed by the Medical Division of the Office of Civilian Defense. Courses have been presented for physicians selected from the faculties of medical schools to be trained as instructors in the medical aspects of chemical warfare. Arrangements are now being made for the presentation of courses by these instructors in their own medical schools.

Training for nonmedical personnel is provided in gas specialist courses which since early December have been presented monthly at War Department civilian protection schools. These schools are located at Amherst College Amherst Mass Purdue University, Lafayette Ind Loyola University New Orleans, Occidental College, Los Angeles, Stanford University, Palo Alto, Calif, and the University of Washington, Seattle.

DEHYDRATED FOODS COOKBOOK

A cookbook dealing exclusively with the preparation of dehydrated foods has been published, the War Department announced on February 4, for the use of army cooks, and will not be available to the public at present. The Quartermaster General in Chicago and commercial organizations which have pioneered in the dehydration of foods collaborated in producing the manual, which contains recipes for cooking dehydrated apples, beets, cabbage, carrots, white potatoes, sweet potatoes, rutabagas and eggs, and also recipes for pies, cakes and puddings using dehydrated foods as ingredients. Quartermaster Corps subsistence experts state that dishes prepared according to directions from satisfactory dehydrated foods usually cannot be distinguished from those prepared from fresh materials. Dehydrated foods have decided advantages in that shipping weight of dried products is only a fraction of that of the original food. This is of particular advantage now, when shipping tonnage and space must be conserved.

ARMY TAKES OVER WILLIAM WIRT WINCHESTER HOSPITAL

The 160 bed William Wirt Winchester Hospital New Haven, Conn which was established in 1918 as a tuberculosis hospital, has been leased as an army hospital for the period of the national emergency. The need for an army hospital at this location became imperative with the recent growth of the army in school at Yale University. The William Wirt Winchester Hospital was used by the army during World War I but has been vacant since 1940. Together with the building, which costs about \$1,325,000 is 44 acres of land.

GRADUATES OF SPECIAL TRAINING COURSE

Fifty-six officers of the Medical Department of the Army graduated at the Medical Field Service School Carlisle Barracks Pa February 5 from a special training course and left immediately for assignments in the medical battalions of infantry divisions now being activated. Thirty-two officers of the class had previously graduated from a basic course at the school, the only service school training Medical Department officers for field duty. Of the fifty-six officers, forty-six hold commissions in the Medical Corps, eight in the Medical Administrative Corps and one each in the Dental and Veterinary Corps. Four of the officers are majors, twenty-five are captains, twenty-two are first lieutenants and five are second lieutenants. New York had the largest number in the class with thirteen and Ohio was second with six. The scope of the course was broad since the officers will range in posts from commanding officers of the battalion to supply officers. Another class arrived February 8 to begin another special training course.

The Gas Protection Service of the U S Citizens Defense Corps has been organized as follows. The Medical Division of the Office of Civilian Defense has a gas protection section responsible for organization and training for gas defense. This section functions through the nine civilian defense regions, which are coterminous with the service commands of the U S Army. Regional gas officers have been designated for several of the coastal regions to supervise and assist the state gas consultants and the senior gas officers of defense councils in the organization of state and local programs. The senior gas officer trains gas reconnaissance agents who serve in each zone of the city. These men are responsible for the identification of the agent, the collection of samples, the prevention of casualties, the delimiting of gassed areas and cooperation with the Emergency Medical Service, the health department and other agencies concerned in protection against gas.

Instructions to members of the U S Citizens Defense Corps on their duties in gas defense have been issued by the U S Office of Civilian Defense in Operations Letter No 104 (Supplement 3 to Operations Letter No 42), dated January 11

DUTIES OF EMERGENCY MEDICAL SERVICE

For the Emergency Medical Service the duties are set forth as follows

Duties Before Gas Attack—1 Plan with assistance of senior gas officer for the establishment of gas cleansing stations for cleansing gassed patients with other injuries and for cleansing of civilian protection personnel Each hospital of 150 beds or more should be provided with a cleansing station Cleansing stations should be available in the ratio of one per 50 000 of population and should be located at smaller hospitals or casualty stations where 150 bed hospitals are not available in this ratio

2 Recruit, train and assign personnel to gas cleansing stations for cleansing services

3 Provide instruction, in cooperation with the senior gas officer, for general public and civilian protection personnel in self protection and self cleansing (Operations Letter 46)

4 Provide for instruction of physicians in diagnosis and treatment of chemical casualties

5 Assist hospitals in planning for handling of gas casualties

6 Assure adequate distribution of protective clothing and gas masks and other protective equipment to members of mobile medical teams and train personnel in their use

7 Make provision for training drivers of ambulances and sitting case cars in protection of their equipment against liquid gas contamination, inform them of arrangements for vehicle decontamination by Emergency Public Works Service

8 Arrange for the protection from contamination of the equipment used to transport contaminated casualties as far as it is possible

Duties During Gas Attack—1 On advice of the senior gas officer and under the orders of the commander, man the gas cleansing stations

2 Advise other services of the U S Citizens Defense Corps in regard to first aid cleansing of their personnel

3 Assign a mobile medical team to gas cleansing stations for first aid

Duties After Gas Attack—1 Evaluate the effectiveness of the cleansing procedures which have been used

2 Provide follow-up treatment of patients

3 Prepare inventory of protective equipment available for use in future attacks and obtain additional equipment as necessary

4 Cleanse bodies of the dead to facilitate identification

FUNCTIONS OF HEALTH DEPARTMENT

Important functions assigned to the health department in the local program of gas defense are as follows

Duties Before Gas Attack—1 Provide for analyses for war gases in samples of food and water These tests may be performed in a local health department if laboratory facilities are adequate In such case it is desirable to utilize the same laboratory facilities for the analysis for war gases of air and other materials Where laboratory facilities other than those of the local health department are more suitable for use in the analysis of war gases, arrangements should be made by the local health department for the analysis of samples of water and food

2 Advise the senior gas officer regarding the nature of instructions to the public concerning precautions to be taken in the event of water supply contamination Such instructions are to be promulgated by the health officer

3 Cooperate with waterworks officials in planning for the protection and decontamination of the water supply

Duties During Gas Attack—1 Collect samples of food and water for laboratory analysis if contamination is suspected

2 Inform the public regarding contamination of food and water supplies including recommendations in regard to self protection

Duties After Gas Attack—1 Decontaminate, destroy or otherwise provide for the handling and disposal of contaminated food supplies

2 Assist the waterworks in the treatment of contaminated water supplies

3 Advise the senior gas officer in regard to the safety of the public water and food supplies and inform the public regarding contamination of such supplies and methods of dealing with it

4 Obtain reports of analysis of samples of water or food and take appropriate action Save specimens of contaminated water and food for transmission whenever necessary to a Chemical Warfare Service or other laboratory by the senior gas officer

Gas masks are now being distributed to the personnel of the protective services As a guide to local distribution and care of masks, the Office of Civilian Defense issued Operations Letter No 106, January 20 which was published in *THE JOURNAL* February 6 page 438

SIMPLIFICATION OF EMERGENCY MEDICAL SERVICES

The Office of Civilian Defense Washington D C has according to the Washington *Evening Star* recommended to local defense councils a simplified plan of operating their emergency medical services James M Landis director of the Office of Civilian Defense recommended a reduction in the number of casualty stations for the slightly injured and the abolishing of most first aid posts at the scene of accidents and all first aid parties as such The District of Columbia at that time had seventy eight casualty stations Mr Landis said that the British have found that more lives can be saved if the bombing victims are treated at the scene of the incident only for the arrest of the hemorrhage and the treatment of shock and then only by doctors or nurses or by rescue workers directly under them Many preconceived notions concerning first aid have been dispelled by the experiences of Great Britain under air raid conditions Most of the victims of air raids are severely injured or dead, having been crushed under the debris of demolished buildings and less than one third are slightly injured and can be cared for at the casualty stations, as the severely injured must go to a hospital Under the new plan recommended first aid would be limited to a few simple measures administered at the scene by medical personnel or a rescue team under professional direction

CIVIL AIR PATROL WILL TRANSPORT PLASMA IN EMERGENCIES

James M Landis U S director of civilian defense has arranged for the Civil Air Patrol to fly blood plasma supplies into stricken areas in the event of emergencies the Medical Division, Office of Civilian Defense announced in circular Medical Series No 27, February 1

In instances in which it becomes necessary to supplement local stocks of plasma for the treatment of casualties caused by bombing fire tornado or other disaster and other methods of transportation are not available or are inadequate the regional medical officer of civilian defense is instructed to get in touch with the appropriate wing commander of the civil air patrol and request emergency transportation for the plasma Wing commanders have been authorized to accept such requests only from the regional medical officers

These arrangements apply for all states except those located within the jurisdiction of the Western Defense Command the circular states It is understood that in those states the Western Defense Command has sufficient nontactical airplanes available to furnish such transportation

CIVILIAN DEFENSE PERSONALS

Dr Hamilton Southworth New York, recently joined the staff of the Medical Division of the Office of Civilian Defense Washington D C, as a member of the scientific development and research section Dr Southworth who has been commissioned in the grade of surgeon in the U S Public Health Service, was expected to go to London to represent the Medical Division as an intelligence officer He is a graduate of Yale University and of Johns Hopkins University Medical School,

Baltimore, and since 1937 has been assistant in medicine at Columbia University College of Physicians and Surgeons, New York, and assistant physician at the Presbyterian Hospital and the New York Neurological Institute

Eugene W. Scott, Ph.D., research assistant at the Kettering Laboratory of Applied Physiology, University of Cincinnati, has been appointed gas officer in the Medical Division of the Office of Civilian Defense. Dr. Scott, a graduate of the University of Illinois at Urbana, received his doctorate in 1931 at Cornell University, majoring in organic chemistry, optical chemistry and biochemistry.

Amos J. Alter, sanitary engineer of the Indiana State Board of Health, Indianapolis, has been commissioned assistant sanitary engineer in the U. S. Public Health Service Reserve and

assigned to the Medical Division of the Office of Civilian Defense in Washington. Mr. Alter graduated from Purdue University School of Civil Engineering, Lafayette, Ind., and later did postgraduate work in public health engineering at the University of Michigan, Ann Arbor.

Ralph E. Tarbett, who has been chief sanitary engineer of the Office of Civilian Defense in Washington since August 1941, has been recalled to the U. S. Public Health Service by the Surgeon General, where he will assume the direction of the federal facility security program as it relates to domestic water supplies, and sanitary engineer Gordon E. McCallum has been designated as the acting chief engineer in his stead. Mr. McCallum has been an officer of the Public Health Service since 1939.

MISCELLANEOUS

PROCUREMENT OF SANITARY ENGINEERS

Paul V. McNutt, chairman of the War Manpower Commission, has taken steps to provide for the effective distribution of sanitary engineers among the Army, Navy, Public Health Services and state and municipal agencies. To locate and assign such personnel to the war services, Mr. McNutt established a committee within the Procurement and Assignment Service for physicians, dentists and veterinarians. The chairman of the committee is Abel Wolman, professor of sanitary engineering at Johns Hopkins University and chairman of the National Research Council's committee on sanitary engineering. This committee was established at the request of the Surgeon Generals of the Army, Navy and Public Health Service.

Professor Wolman will sit as a member of the directing board of the Procurement and Assignment Service, the other members of the committee are:

Kenneth F. Macey, secretary, professor of epidemiology, School of Hygiene and Public Health, Johns Hopkins University, Baltimore.

Harold E. Babbitt, professor of sanitary engineering, University of Illinois, Urbana.

F. C. Bishopp, assistant chief, Bureau of Entomology and Plant Quarantine, U. S. Department of Agriculture.

V. M. Ehlers, chief engineer, Texas State Board of Health, Austin.

Gordon M. Fair, professor of sanitary engineering, Harvard University, Cambridge, Mass.

H. A. Whitaker, chief engineer, Division of Sanitation, Minnesota State Department of Health, Minneapolis.

J. K. Hoskins, senior sanitary engineer, U. S. Public Health Service, Washington, D. C.

Because the National Research Council committee already had considered the difficulties found in the procurement and assignment of sanitary engineers for military and civilian groups in the United States and foreign countries and had begun a canvass to determine the availability of the engineers and the prospective demands for them, Mr. McNutt asked its members to serve on the new committee. (THE JOURNAL, January 9, p. 138)

NURSES WANTED FOR CIVILIAN AND MILITARY NEEDS

Sixty-five thousand young women must enter schools of nursing between June 30, 1943 and July 1, 1944 if even minimum civilian and military needs of the nation are to be met, Paul V. McNutt, Federal Security Administrator, announced on January 14. This quota which exceeds the previous year's quota by 10,000, was reached at a meeting in Washington of the subcommittees on nursing and hospitals of the health and medical committee, Office of Defense Health and Welfare Services. Where state laws permit, schools of nursing are urged to accelerate their courses to reduce the usual training period from three years to thirty months, and in some instances even a little shorter time. In most cases a college degree subtracts nine months from the course. Federal and private scholarships for nursing education are available. Details regarding entrance requirements may be secured from the National Committee on Recruitment of Student Nurses, 1790 Broadway, New York. In general the following are basic qualifications required of an entrant. She must be between 18 and 35 years old, physically fit and have at least a high school education. She may be either married or single.

PUBLIC HEALTH UNDER HITLER

DNB of Dec. 10, 1942 reports from Lvov the establishment of an institution to protect Europe from the dangers of health which threaten from the east. This is a great typhus (flekkfieber) research institute which bears the name of Emil von Behring.

Besides the governor general Reich Minister Dr. Frank and numerous representatives of state, armed forces and party, a large number of scientists from all parts of the Reich and representatives of the Italian and Hungarian armed forces were present at the solemn ceremony. The governor general announced that the Fuehrer had awarded on the occasion of the ceremony the War Merit Cross (first class) to two important pioneers of medical science and research in the general government. Dr. Robert Kudicke and university assistant Dr. Wohlrab, who had earned special merit for their work in combating typhus. Prof. Dr. Blome, as representative of Reich Health Leader Dr. Conti, conveyed the latter's greetings and then gave a survey of the origin and combating of epidemics in wartime. After thanking the administration and the doctors for the successful work done in the field of health, Prof. Dr. Blome declared that the Lvov Institute was to be developed into the greatest typhus institute in the whole world. At the end of the ceremony those present went round the new research institute, which has already started work.

Reports from Riga in DNB of Dec. 8, 1942 state that efforts are being made to combat typhus, which had its greatest hold in Lithuania and White Russia. Last year's outbreak could be kept within bounds, and precautions are being taken to check any fresh outbreak in its initial stage. This is being done largely by delousing the population. A special medical school has also been founded in Riga and there can be no fear of an epidemic now.

According to Bersen of Dec. 1, 1942 the scarlet fever epidemic has now reached general hospitals. "Far patients from St. Joseph's Hospital, who were infected with scarlet fever, have been transferred to the isolation hospital. Eight children from Bolbro Children's Home have been removed to Middlefort Hospital because the Odense isolation hospital is full.

According to Hvas of Dec. 10, 1942 an agreement has been reached between the French and the German authorities regarding the repatriation of sick or wounded French prisoners who have been found unfit for military service for at least a year. The repatriation is to be carried out in accordance with the provisions laid down by the Geneva Convention. The French prisoners' physical state of unfitness has to be decided by a medical commission. It is brought to the knowledge of any whom it may concern that the German authorities do not accept individual applications.

According to *Medizinische Welt*, Berlin, Oct. 31, 1942, in a lecture in Breslau Professor Kathe spoke about food poisoning. In spite of strict regulations to prevent poisoning from contaminated food there had been a severe epidemic of meat poisoning, and five deaths had occurred through infections with the bacillus Newport.

It is stated in the *Zeitschrift für Parasitenkunde*, Berlin, 1941, in an article on trichinosis by Lehmannsick and Sendisaya, that two great epidemics of trichinosis had occurred in the German army, one in Poland and the other in Norway.

ORGANIZATION SECTION

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status—H R 1749 has been reported to the House, proposing to grant medical and hospital treatment, domiciliary care and burial benefits, now available to veterans of World War I, to any officer, enlisted man or woman, member of the Army Nurse Corps (female) or Navy Nurse Corps (female) employed in the active military or naval service of the United States on or after Dec 7, 1941 and before the termination of the present war

Bills Introduced—The President has submitted to the Congress a supplemental estimate of appropriation for the Children's Bureau for the fiscal year 1943 in the amount of \$1,200,000 for grants to states to provide, in addition to similar services otherwise available, medical, nursing and hospital maternity and infant care for wives and infants of enlisted men in the armed forces of the United States of the fourth, fifth, sixth or seventh grades. From the funds recommended, it is contemplated, payments will be made to physicians for obstetric care, hospital and nursing services, and payment for medical care of infants. S 654, introduced by Senator Reynolds, North Carolina, proposes to establish a Chiropody Corps in the United States Army. Appointees will be required, the bill provides, to pass a similar physical examination as provided for the appointment of officers of the Medical Corps and a professional examination to include tests of skill in practical chiropody and proficiency in the usual subjects taught in schools of chiropody. S 668, introduced by Senator Bilbo, Mississippi, and H R 1706, introduced, by request, by Representative Lesinski, Michigan, propose to authorize the Veterans' Administration to provide vocational rehabilitation and assistance in securing suitable employment for service connected disabled veterans. S 662, introduced by Senator Bilbo, Mississippi, would authorize pensions for certain physically or mentally helpless children. S 655, introduced by Senator Thomas, Oklahoma, proposes to establish a United States Medical Academy for the training and instruction of persons in a manner which will best fit them for the performance of service as commissioned officers in the medical branches of the military and naval forces of the United States. H R 1673, introduced by Representative Walter, Pennsylvania, proposes a federal appropriation of \$1,500,000 to construct a veterans' hospital in the eastern part of the state of Pennsylvania for the treatment of general medical and surgical disabilities, the hospital to have a capacity of at least 400 beds. H R 1696, introduced by Representative Reed, New York, proposes to exempt certain religious, charitable, scientific, literary and educational organizations from the requirement of withholding the victory tax. H R 1764, introduced by Representative Green, Florida, proposes to authorize an appropriation of \$10,000,000 to acquire a site and to build thereon a naval hospital in Florida to accommodate 1,000 bed patients. H R 1754, introduced by Representative Miller, Connecticut, proposes to authorize an appropriation of \$350,000 to enlarge the veterans' administration facility at Newington Conn, to increase its capacity to provide accommodation for a total of approximately 500 bed patients.

STATE MEDICAL LEGISLATION

Arkansas

Bill Introduced—S 64 to amend the basic science act, proposes that the basic science board must waive examination on recommendation of any of the various boards authorized to issue licenses to practice the healing art or any branch thereof, provided such recommendation specifies that the applicant has passed an examination in the basic sciences before a board authorized to issue licenses to practice the healing art in some other state.

California

Bills Introduced—S 879, to amend the unemployment insurance act proposes regulations for the establishment of a system of social insurance. S 885, to amend the unemployment insurance act, proposes regulations for the establishment of a system of disability unemployment insurance. A 1079 to amend the unemployment insurance act, proposes the establishment of a system of compulsory health insurance. A 1110, to amend the business and professions code proposes the creation of a board of examiners for chiropody defined as the diagnosis, medical, surgical, mechanical, manipulative and electrical treatment of the human foot, including the nonsurgical treatment of the leg. No chiropodist shall do any amputation or use any anesthetic other than local. A 1171, to amend the business and professions code, proposes the appointment by the board of medical examiners of committees to determine the following: (1) whether an applicant fulfils all the requirements for the certificate for which he is applying, (2) whether an applicant shall be admitted to an examination and the terms and conditions of his admittance, (3) whether a recommendation should be made to the members of the board that the certificate applied for be issued. A 1174, to amend the business and professions code proposes conditions under which a person whose certificate has been revoked or suspended for more than one year may be reinstated. A 1175, to amend the business and professions code proposes that applicants for a license to practice medicine must have received a diploma from an approved school. A 1191 to amend the welfare and institutions code proposes that no person shall maintain an establishment for the mentally ill without having obtained a license from the state department of institutions. A 1499, to amend the labor code, proposes that when an employee is dissatisfied with the medical treatment he is receiving from a physician furnished by the employer he may at the expense of the employer, receive the services of a consulting physician and such other physicians as the consulting physician may designate.

Connecticut

Bills Introduced—S 461, to amend the workmen's compensation act, proposes to repeal the section authorizing employers to accept waivers from employees with physical defects. Substitute for S 486, to amend the osteopathic law, proposes to extend the scope of osteopathy to entitle an osteopath to use antiseptics, sedatives and narcotics, endocrines, vitamins and vaccination and to perform such diagnostic procedures as are taught in schools of osteopathy approved by the state board of osteopathic registration and examination, provided that no osteopathic physician shall be authorized to compound a prescription for drugs other than the above for internal medication. Substitute for H 313, proposes that no articles having special utility for the prevention of conception shall be sold at retail except in a store under the supervision of a licensed pharmacist, but any person registered for the practice of medicine in Connecticut may prescribe contraceptive devices for a married woman where her life or health would be endangered by further pregnancy. Substitute for H 591 proposes regulations for the establishment of a Connecticut Cash Sickness Compensation Act. H 717 proposes that no doctor shall charge over \$2 for an office call or over \$5 for a house call.

Delaware

Bill Introduced—H 97 to amend the workmen's compensation act, proposes to authorize an employee to engage a physician or surgeon other than the one furnished by the employer and to receive from the employer the reasonable cost of such services.

Georgia

Bill Introduced—H 138 proposes to authorize the state board of health to license maternity homes and adopt rules and regulations governing and protecting the standards of service therein and to make rules and regulations concerning the certification of midwives

Idaho

Bill Passed—H 43 passed the senate on February 5. It proposes that each applicant for a marriage license produce a certificate signed by a licensed physician certifying that the applicant has been thoroughly examined and is not infected with syphilis in a communicable stage. The physician making the examination may not charge more than \$2.

Indiana

Bills Introduced—S 135 proposes to prohibit school authorities from employing food handlers who are addicted to drugs or who have tuberculosis or syphilis in an infectious stage and to require all school employees to undergo a physical examination for tuberculosis at least once every three years by a duly licensed doctor of medicine. S 177 proposes the creation of a state board of natural therapeutic physicians, the practice of natural therapy being defined as diagnosis and treatment of human ailments as taught in chiropractic, naturopathic and physiotherapy schools. H 317, to amend the vital statistics act, proposes that the state board of medical registration and examination may revoke the license of a physician who has failed to comply with its terms. H 326 proposes to require persons maintaining a nursing or boarding home for aged persons to obtain a license therefor. H 357 proposes the furnishing of necessary medical care to the parents of dependent children. H 393 to amend the medical practice act proposes to eliminate the provision authorizing the attorney general to make use of the injunctive process in enforcing the act. H 413 proposes that every person employed in a place serving food shall secure a certificate from the health officer showing freedom from contagious infectious and communicable diseases and limits the health officer to a fee of \$2 for such certificate and examination. H 440 proposes the following definitions: (1) chiropractic—the science of locating and adjusting the subluxations of the articulations of the human spine and its adjacent tissues; (2) physical therapy—the practice of healing or the administering to and treating of the sick and suffering by means of natural and physical agents; (3) naturopathy—the process or system whereby remedies for disease are discovered and whereby said remedies are applied to the healing of disease without drugs which employs various methods to assist nature in repelling the disease; (4) mechanical therapy—the treatment of disease by mechanical means; (5) electrotherapy—the use of electricity for therapeutic purposes and (6) hydrotherapy—the use of water for therapeutic purposes.

Bills Passed—S 4 passed the senate on February 6. It proposes the enactment of a law to license and regulate nursing homes. H 66 passed the house on February 5. It proposes the enactment of a law regulating the operation of plants for the cold storage of food in individual lockers. Among other things the bill proposes that all employees of such locker plants shall undergo a semiannual health examination by a physician and requires the employer to keep such health certificates on file at all times.

Kansas

Bills Introduced—S 112 proposes to authorize the establishment of experimental classes to test the merits of the science of psychophonophysics. S 122 proposes to authorize the release of a person from an insane asylum on the basis of a certificate that he has undergone an operation which has eliminated his carnal tendencies.

Maine

Bills Introduced—S 175 proposes that the fees of expert witnesses in homicide cases shall be paid by the state. H 259 to amend the act relating to infectious and communicable diseases proposes to require every physician to report all cases of syphilis, gonorrhea, chancroid and lymphogranuloma venereum which come to his knowledge. H 328 proposes among other things, to authorize the state board of registration of medicine

to issue temporary emergency certificates to qualified physicians now licensed to practice in other states. H 632, to amend the premarital examination law, proposes that applications for marriage by a member of the armed forces will be accepted if accompanied by a report of a physical examination by any doctor of the armed forces.

Maryland

Bill Introduced—H 209, to amend the medical practice act, proposes to authorize the board to grant temporary permits to practice medicine to qualified persons.

Bill Passed—S 84 passed the senate on February 3. It proposes to amend the medical practice act by eliminating the proviso that no two courses of medical lectures shall be either begun or completed within the same calendar year. This amendment is apparently for the purpose of enabling graduates of accelerated medical courses to obtain licensure in Maryland.

Massachusetts

Bill Introduced—H 864 proposes to authorize the department of public welfare to grant licenses for the maintenance of convalescent or nursing homes.

Michigan

Bills Introduced—S 3 to amend the divorce laws, proposes to authorize the granting of divorces on the ground of insanity. H 99, to amend the chiropractic act proposes to extend the scope of chiropractic to include the diagnosis and treatment of diseases and injuries by the use of air, light, heat, cold, water, electricity, diet, physiotherapy and all necessary hygienic and sanitary measures incident to the care of the body, and to authorize chiropractors to sign death and health certificates and report to the health officer the same as all other persons authorized to do so under the public health laws. No chiropractor, however, shall be entitled to practice medicine or surgery. H 100 proposes that the services and facilities of all state laboratories shall be available to all licensed members of the healing professions without discrimination.

Minnesota

Bill Introduced—H 273 proposes that physicians in the armed forces shall not be required to renew their annual licenses during the term of such service and shall be exempt from payment of all renewal fees.

Bill Enacted—H 160 has become chapter 16 of the Laws of 1943. It requires maternity hospitals to file a written report with the director of social welfare of the birth of any child known or believed to be illegitimate within twenty-four hours after the birth occurs.

Missouri

Bill Introduced—H 134 proposes that it shall be the duty of every attending or consulting physician having charge of any minor under the age of 6 who is totally deaf or whose hearing is impaired to report that fact to the state superintendent of public schools and furnish such information as the superintendent may request.

Bill Passed—H 45 passed the house on February 9. It proposes to amend the marriage law by requiring any person applying for a license to marry to furnish a report of a negative laboratory serologic test for syphilis and an affidavit signed by him or herself that he or she is free from syphilis. If the laboratory test is positive the applicant must present a certificate from a physician licensed to practice in the state of Missouri certifying that the applicant is not infected with syphilis in a communicable stage.

Montana

Bill Introduced—S 63 proposes to authorize certain institutions of higher learning in Montana to obtain custody of unclaimed human bodies for use in the teaching and demonstration of anatomic science by professional instructors.

Nebraska

Bills Introduced—L B 243, to amend the chiropractic law proposes to define chiropractic as the science of locating and removing interference with the transmission of nerve energy without the use of medicine or surgery. L B 274, to amend

the medical practice act proposes to eliminate the requirement that no one of the necessary four courses of lectures of eight months each may be given within one year and to provide only that they may not be given concurrently. The purpose of this proposal is apparently to enable graduates of accelerated medical courses to obtain licensure in Nebraska. L. B. 279 to amend the medical practice act, proposes that no licensee shall be required to pay annual renewal fees while in the military service of the United States.

New Hampshire

Bill Introduced—H. 267, to amend the medical practice act proposes to authorize the board of registration in medicine to issue licenses to practice physiotherapy defined as the treatment of any person by physical means including the use alone or in combination of massage, heat, light, water or electricity, or by any laying on of the hands for the purpose of effecting relief or cure of any injury or physical ailment.

Bill Passed—H. 54 passed the house on January 28. The bill proposes the establishment of a state department of health to take over the powers and duties of the state board of health.

New Jersey

Bill Passed—A. 93 passed the assembly on February 1. The bill proposes to amend the medical practice act by granting an extension of two years within which a licensee must furnish proof of his actually having become a citizen.

New Mexico

Bills Introduced—H. 65 proposes that all applicants for a marriage license shall file a certificate from a physician and surgeon duly licensed to practice medicine and surgery in the state of New Mexico certifying that the applicants are free from syphilis in a communicable stage. H. 71 proposes the creation of a state board of therapeutic physicians and defines natural therapy as the diagnosis and treatment of human ailments, the manual and mechanical manipulation of the human body, the correction of feet, the use of biochemistry, herbal remedies, cell salts, diet and all material health sciences, and the application of heat, cold, air, water, light, electricity, radiant energy and exercise in the treatment of disease, injury or deformity, and for relaxing muscles, restoring normal circulation and function and regulating body chemistry, physiotherapy, electrotherapy, physicaltherapy, hydrotherapy, colorotherapy [sic] and first aid in emergencies.

New York

Bills Introduced—S. 278 proposes to authorize the state commissioner of health to employ necessary medical and health personnel for rendering services in areas designated by the governor as being emergency health and sanitation areas by virtue of an inadequacy of medical facilities or personnel therein. Compensation to such employed medical personnel may be paid by the state department of health. A. 604 proposes that all railroads and other public carriers shall carry a first aid kit for the convenience of the passengers should an emergency arise. A. 636, to amend the workmen's compensation act, proposes to require an employer to furnish medical care to an employee mentally disabled as the result of an occupational injury.

North Carolina

Bill Introduced—S. 95 proposes the creation of a board of naturopathic examiners. No definition of naturopathic practice is stated, it being provided only that a naturopath shall not practice any other treatment authorized or provided for by law for the cure and prevention of disease or ailments.

North Dakota

Bill Introduced—H. 131 proposes the creation of a board of naturopathic examiners and defines naturopathy as the art and science of applied therapy as heretofore or hereafter taught in the recognized schools and colleges of naturopathy, except materia medica and major surgery.

Bill Passed—S. 63 passed the senate on February 9. It proposes to prohibit the sale of barbitals except on a written prescription by a doctor of medicine, doctor of dental surgery or doctor of veterinary medicine lawfully practicing his profession in the state.

Ohio

Bills Introduced—H. 95 to amend the medical practice act proposes certain changes in the causes and procedure for revocation of a license. H. 244 to amend the enabling act relating to the establishment of medical service plans proposes that physicians in the armed forces shall be considered as residing and actively practicing in the county in which they previously resided and proposes further that no certificate, authority or license to operate a medical service plan under the enabling act shall be issued for the duration of the war or within six months thereafter.

Oklahoma

Bills Introduced—S. 90 to amend the income tax law proposes to authorize taxpayers to deduct expenses for physicians' fees, hospital bills, nurses' fees, ambulance charges and all other medical expenses. H. 222 to amend the medical practice act proposes that the members of the board of examiners must be citizens.

Oregon

Bills Introduced—S. 119 to amend the workmen's compensation act proposes to redefine occupational injury so as to include occupational diseases peculiar to the trade or occupation in which an employee was engaged and due to causes in excess of the ordinary hazards of employment. H. 193 to amend the law relating to the examination of handicapped children, proposes to authorize eye examinations of such children to be made by qualified and licensed oculists or optometrists. H. 245 proposes to require persons maintaining a hospital for the treatment of persons with mental disorders or mental defects to obtain a license from the state board of health. H. 303 to amend the workmen's compensation act proposes to authorize an injured employee to receive treatment by a Christian science practitioner in lieu of medical treatment unless the employer has elected not to be subject to such provision.

Bills Passed—S. 91 passed the senate on February 4. It proposes to amend the osteopathic practice act by requiring osteopaths to register annually. H. 222 passed the house on February 4. It proposes to amend the chiropractic law to require chiropractors at the time of the annual renewal of their licenses to present proof that they have attended a two day educational program conducted by the Oregon chiropractic association.

Bill Enacted—H. 32 was approved by the governor on February 2. It repeals the law relating to the office of state bacteriologist who was authorized to make scientific studies and investigations of animal and plant diseases.

Pennsylvania

Bill Introduced—H. 161 proposes conditions for the compulsory and voluntary sterilization of persons afflicted with any presumably hereditary form of mental deficiency on the certification of qualified physicians. Excepted from the proposal would be sterilizations performed for therapeutic reasons such as tuberculosis, heart disease, tumors or infections.

Rhode Island

Bill Introduced—S. 42 as amended to amend the basic science law, proposes to exempt from the operation of the act all persons who had on April 27, 1940 already commenced the study of one of the healing arts at an approved school.

South Carolina

Bill Passed—H. 33 to amend the medical practice act passed the house on January 27 and the senate on January 28. The proposal would remove the existing requirements that no two of the required four full courses of lectures of at least twenty-six weeks may be given in the same year. The purpose of this proposal is apparently to enable graduates of accelerated medical courses to obtain licensure in South Carolina.

South Dakota

Bill Introduced—H. 84 to amend the workmen's compensation act proposes to add necessary first aid treatment to the services to be furnished by the employer.

Bill Passed—H. 32 passed the senate on February 5. It proposes that osteopaths be required to renew their certificates.

to practice annually and to submit evidence, at the time of such renewal, of attendance of at least two days at the annual educational program conducted by the South Dakota state osteopathic association during the preceding year

Tennessee

Bills Introduced—S 460 proposes an enabling act to provide for the organization, operation and regulation of nonprofit corporations desiring to operate a nonprofit hospital service plan. Hospital service and hospital care are defined as including bed, board, use of operating room, ordinary medications, surgical dressings and other routine procedures approved by the state board of health, and general nursing care. S 490, to amend the unemployment compensation act, proposes that the term employment shall not include services performed as an intern. S 506, to amend the pharmacy law, proposes conditions under which a person has been engaged in conducting a drug store for twenty-three successive years may be authorized to compound and fill physicians prescriptions and be licensed as a pharmacist without examination. H 640 proposes the repeal of the existing premarital examination law. H 700, to amend the workmen's compensation law, proposes a list of some fifteen occupational diseases which shall be included within the meaning of injury or personal injury arising out of the course of a person's employment. H 702, to amend the workmen's compensation law, proposes to enlarge the definition of injury and personal injury so as to include such occupational diseases or infections as arise naturally out of such employment or as naturally and unavoidably result from such accidental injury. The present law only covers occupational diseases naturally arising from the injury. H 903 to amend the workmen's compensation act, proposes that the employer shall designate a group of three or more reputable physicians or surgeons from which the injured employee shall have the privilege of selecting the operating surgeon or the attending physician.

Bills Passed—H 39 passed the house on February 5. It proposes that hospitals and physicians called on to render aid to persons suffering from any wound or other injury inflicted by means of a knife, pistol, gun or other deadly weapon or suffering from the effects of poison or suffocation shall report the same immediately to the chief of police. H 129 passed the senate on January 28, a bill proposing the creation of a state board of naturopathic examiners. Naturopathy is defined as the prevention, diagnosis and treatment of human injuries, ailments and diseases by means of any one or more of the psychologic, physical or mechanical, chemical or material forces or agencies of nature. H 323 passed the house on February 2. It proposes to authorize a coroner, when requested so to do by the district attorney general, to summon as a witness a surgeon or physician to make an examination of the body of a deceased, including the performing of an autopsy and to give a professional opinion thereon, the fee for which is not to exceed \$25. H 420 passed the house on February 2. It proposes to prohibit the sale or advertisement of articles used for the prevention of conception without a license issued by the state board of pharmacy, except that physicians and medical practitioners regularly licensed to practice medicine or osteopathy in the state of Tennessee would not be prevented from prescribing such articles.

Texas

Bill Introduced—H 274 proposes the creation of a state board of examiners in the basic sciences to examine persons desiring to take an examination for a license to practice the healing art in the subjects of anatomy, physiology, chemistry, bacteriology, pathology and hygiene and public health.

Utah

Bill Introduced—S 100 proposes to make it unlawful for any person to maintain a maternity hospital without having first obtained a license from the state board of health.

Bill Passed—H 29 passed the house on January 29. To amend the medical practice act, it proposes to authorize the issuance of two different types of naturopathic licenses, (1) to

practice as a naturopathic physician without the use of drugs and without surgery and (2) to practice as a naturopathic physician and surgeon including obstetrics.

Vermont

Bills Introduced—S 12, to amend the chiropractic law, proposes to require chiropractors to attend a four year, rather than a three year, course of study. H 50, to amend the medical practice act, proposes to repeal the section setting forth the requirements for admission to practice and to substitute therefor an authorization that the board shall make rules and regulations covering requirements for admission to practice medicine and surgery.

Bill Passed—H 49 passed the house on February 3. It proposes to authorize the state board of medical registration to issue temporary emergency certificates to physicians licensed outside the state if found qualified to practice in the state during the emergency.

Washington

Bill Introduced—H 136 proposes that hospitals exempt from taxation because of their charitable status shall permit all physicians and surgeons in good standing with the American Medical Association to use their hospital facilities without discrimination.

Bill Passed—S 76 passed the senate on February 4. It proposes to exempt members of the armed forces from being required to continue in full force and effect their license to practice a profession in the state. Such may be renewed within six months after an honorable discharge.

West Virginia

Bills Introduced—S 36 proposes the creation of a division of cancer control in the state department of health to administer provisions relating to the diagnosis, treatment and care of persons suffering from cancer, including the conduct of an educational program, the establishment of cancer clinics in general hospitals throughout the state and the furnishing of tissue diagnostic service to all patients. S 71 and H 120 propose the enactment of enabling legislation for the creation of nonprofit hospital service corporations. H 16 to amend the sales tax law, proposes to exempt therefrom the sales of medicines by drug stores on prescriptions signed by a physician.

Wisconsin

Bills Introduced—S 36 proposes to amend the law relating to coroners so as to provide for the appointment of a medical examiner. S 53 proposes to exempt members of the armed forces from being required to maintain a license to practice any profession within the state proposes that this license shall be suspended during the active service of such persons and proposes that it may be renewed within six months after his discharge. S 92 proposes to authorize the rendering of necessary nonsurgical hospital or clinic service to persons committed to an institution. A 65, to amend the basic science law, proposes to authorize the issuance of basic science certificates by the state board of examiners in chiropractic.

Wyoming

Bills Introduced—S 9 proposes to authorize any county to create a county health department and to appoint a full time doctor of medicine licensed to practice medicine in Wyoming to serve as county health officer. H 58 proposes to prohibit the operation of a hospital unless it has secured a license issued by the state board of health. H 77 proposes regulations for the compulsory sterilization of inmates of certain state institutions if the inmates have been found to be insane, idiotic, imbecilic, feeble-minded or epileptic and the probable potential parents of socially inadequate offspring.

Bill Passed—S 2 passed the house on February 1. It proposes to amend the premarital examination law, proposes (1) to require the test to be made of females as well as males (2) to authorize the required certificate to be executed by a physician duly licensed under the laws of the state of Wyoming and engaged in practice therein.

MEDICAL ECONOMIC ABSTRACTS

STATE MATERNITY AND CHILD CARE

The last decade has seen a great increase in the activity of state agencies in supplying medical care to mothers and children. It is not simply that general health services such as public health nursing, education, sanitation and the control of tuberculosis and the venereal diseases has been greatly expanded. During the same period maternal and child health programs have taken on new features and extended old ones.

Maternal and child health care in the various states is distributed among numerous agencies, the most important of which are health departments, welfare, education, labor, state universities and licensing boards. Functions in twelve states are assigned also to other miscellaneous departments.

Education is the principal avenue of approach in the maternal and child health program. This education is directed to the general public and to the mothers and also includes special educational programs for local physicians and dentists. Aid is given in various ways to clinics and other institutions supply medical care. In all, nearly four fifths of the state health departments either supply personnel or financially aid local maternity (antepartum and postpartum) clinics while all but three of them contribute in one way or another to similar facilities for infants and preschool children.

Eligibility for clinic service depends to a large extent on a patient's economic status. While a few states indicate that the service offered is open to all most of them stipulate that only the medically needy—variously defined as 'all who cannot provide service by their own resources', referrals from physicians and social workers, people of county hospital level, 'all midwife cases and those with a maximum income of \$20 per week per couple plus \$3.50 per week for each child—are accepted. On the whole economic restrictions for admission to maternity services are more stringent than for admission to services for children.¹

All state health departments make some health provision for home nursing services for antepartum and postpartum cases, for infants and for preschool children. Only seventeen health departments reported that their medical care programs included attendance at home births. There are thirty-two jurisdictions providing consultant obstetricians to private physicians.

There are few states that now encourage annual examination of all school children. Instead they favor restriction of the number examined with more concentration on correction of defects.

Total expenditures by state governments supplemented by federal aid has increased from \$1,382,400 in 1930 to \$6,172,600 in 1940.

¹ Mountin Joseph W. and Flook Evelyn. Maternity Child Health Activities by State Agencies. United States Public Health Service.

MORTALITY RATES, 1930 TO 1940

While Texas was not admitted to the registration area until 1933, the proportion of the total population included in the death registration area in 1930 was sufficiently large to justify considering the death rates of that area as representative of the entire country. Between 1930 and 1940 the expectation of life at birth of the total population increased from 59.0 to 63.3 years, an increase of 4.3 or 7 per cent. While it has generally been known that the expectation of life at birth has been greatly increased, it has been thought that there was little or no increase during later years. During the last decade however there has been a definite increase in life expectation at all ages starting from about 7 per cent at birth and being from 5 to 6 per cent from 5 to 70 years. There has even been an increase of 2 per cent in the expectation at the age of 80. Some doubt is thrown on these figures because of the inaccuracy of recorded ages in the higher brackets.

A possible side light on the effect of these changes in death rates is given by the fact that if the 1,060,000 white males born in 1940 were exposed to current mortality rates about 614,000 would reach the age of 65, but if the mortality rates of forty years ago prevailed only about 413,000 would reach that age.

While Negro death rates still are higher than those of white persons, the decrease is greater for Negroes than for white persons. The expectation of life at birth increased 3.5 years for white males but 4.4 years for Negro males, the increase for females was 4.3 and 5.7 years respectively.

Large decreases were recorded in the death rates from the principal respiratory causes of death, influenza, pneumonia and tuberculosis. The decline in the death rate from tuberculosis is a continuation of the trend observed during recent decades. The lower rate from pneumonia undoubtedly was the result in part at least, of an increasingly widespread use of serum and drugs in the treatment of this disease. It should be noted however, that the death rate from influenza also decreased very sharply during the past decade. Part of this decrease may be attributed to the fact that although the number of cases of influenza was higher than the average during 1939, the disease was not especially fatal so that the death rate remained relatively low.

While the maternal death rate had shown no decline in the birth registration area previous to 1930 (which was at least partially due to changes in the area itself) during the past decade this rate declined 48 per cent among white mothers and 34 per cent among nonwhite mothers. In 1940 the two rates were 3.2 and 7.7 per thousand live births respectively.¹

¹ Dorn Harold F. Changes in Mortality Rates 1930 to 1940. Pub Health Rep 57: 1858 (Dec 4) 1942.

WOMAN'S AUXILIARY

Arizona

The Auxiliary to the Maricopa County Medical Society held a luncheon, recently, at the Arizona Club. The guest speaker was Cavett Robert and his subject 'Victory Has a Price Tag'. Mrs. Harlan P. Mills, president of the Auxiliary to the Arizona State Medical Society, welcomed the U. S. Army medical officers, wives and stressed the importance of Red Cross work throughout the state.

California

Orange County held a public relations meeting at the home of Mrs. Harry G. Huffman. Mr. Ben H. Read, executive secretary of the Public Health League of California, and Mrs. Walter Egan Foote addressed the meeting.

Members of the Auxiliary to the San Mateo County Medical Society, under the leadership of Mrs. J. Garwood Bridgman, have made sheets for the civilian defense emergency station and handled the canteen work for the San Mateo blood bank. Several auxiliary members were directly responsible for organizing the San Mateo County blood bank.

The Solano County medical auxiliary with a membership of only thirteen, has done outstanding work in establishing and

operating the Vallejo civilian blood bank. Under the leadership of Mrs. Brownlee Perkins, this auxiliary with the assistance of the Medical Society Nurses' Association and prominent members from the community, has financed and operated this blood bank for six months. During April 1942 one thousand persons willing to give blood were signed up by members of the auxiliary.

Pennsylvania

The Huntingdon auxiliary met at the home of Dr. and Mrs. William A. Doebele. Following luncheon, Mrs. F. H. Crumpacker, a missionary from China, gave a talk on her work in that country. Mrs. Crumpacker stressed mostly the poverty and disease prevalent in China. She said that 'The atrocities committed by the Japanese are beyond description'.

The Jefferson auxiliary met at the Elks' Club in Pottsville. Mrs. Lewis R. McCauley, president, presided. The auxiliary voted to sponsor a mobile unit for blood donors to secure blood for the Pittsburgh blood bank. Mrs. John A. Tushum, district councilor, discussed the Medical Benevolence Fund. The auxiliary held a bridge tea in December and contributed the proceeds to the fund.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Epidemic Cerebrospinal Meningitis—For the first time since 1929 the reported incidence of cerebrospinal meningitis during 1942 approached epidemic status in San Francisco. During the year 1942 there were 32 cases reported with nine deaths as compared with the preceding four years when the average of reported cases per year was 6. The last major epidemic in San Francisco was in 1929 when there were 88 cases reported with eighty one deaths. The history of cerebrospinal fever has indicated that there are periods of high incidence recurring at fairly long intervals. Increased reporting continues into 1943. During the month of January there were 16 cases reported to the department of public health of the city and county of San Francisco of which 2 were listed as nonlocal. Among the 16 cases there were two deaths. Twelve of the patients were male and 4 female. The age incidence showed that 4 were in the group under 5 years, 5 in the group 5 to 20 years, 6 over 20 years and 1 in which the age was not stated. Fifteen of the patients were treated in hospitals and 1 patient was treated at home. As to occupation 5 of the patients were listed as in the armed forces and 4 reported as shipyard workers. A release from the department of public health states that at the time of this reporting in February the increased incidence appears to be continuing.

COLORADO

Annual Registration Due Before March 1—Law has been made of the State Board of Medical Examiners of Colorado is required by law to register annually before March 1 with the secretary-treasurer of the board and to pay a fee of \$2 if a resident of Colorado or \$10 if a nonresident. Failure to pay this fee within the time stated automatically suspends the right of a licensee to practice while delinquent. If he nevertheless continues to practice he is subject to the penalties provided by law for practicing medicine without a license. Failure to pay this fee for three consecutive years results in the automatic cancellation of a delinquent practitioner's license to practice.

DISTRICT OF COLUMBIA

Lecture on Tropical Medicine—Col. Richard P. Strong, professor emeritus of tropical medicine, Harvard Medical School, Boston, and now director of tropical and military medicine, Army Medical School, gave a lecture in the Smith-Reed-Russell series, February 3, at the George Washington University School of Medicine. His subject was Tropical Diseases and the War. The Smith-Reed-Russell Society is composed of honor students in the school of medicine and honorary members elected to the society for outstanding achievement.

Personal—Dr. Edgar A. Bocock, medical superintendent of Gallinger Municipal Hospital, was presented with a number of gifts Dec. 15, 1942, to commemorate his fifteenth anniversary as head of the hospital.—William E. Leahy, U. S. director of the Selective Service System for the District of Columbia, was recently awarded the Distinguished Service Medal for 1942 by the Cosmopolitan Club. The award is made annually to the citizen who "has performed the most unselfish service in the community" during the year. Mr. Leahy was a member of the legal counsel that appeared in behalf of the Medical Society of the District of Columbia in the recent trial.—Dr. Winfred Overholser was recently named honorary president of the District of Columbia Occupational Therapy Association.

ILLINOIS

New Central Unit for Typhoid Carriers in Mental Hospitals—Freud Cottage was recently opened at Manteno State Hospital, Manteno, for the exclusive care and treatment of typhoid carriers in mental hospitals and according to the *Welfare Bulletin* is the only unit of its kind in the world. At present there are about 141 carriers accommodated in the new building which is an old ward unit converted into the new Freud Cottage. One wing in Freud Cottage has subdivisions to provide for isolation of typhoid carriers suffering from

additional complicating infections, tuberculosis, pneumonia and other contagious diseases. There is a 10 bed ward for special research in the cure of typhoid carriers and 2 and 4 bed wards to provide for special behavior problems and mental conditions requiring separate care. The entire project stemmed from the typhoid epidemic at the Manteno State Hospital in 1939, when an intensive epidemiologic study with special reference to the source of infection was carried out. The emergency recommendation for a feces and urine survey of all patients in all the mental institutions resulted in the isolation of still other typhoid carriers. Freud Cottage is the fulfillment of a decision by the state departments of health and public welfare to centralize all these patients. Men and women patients are now cared for in Freud Cottage but it is later expected to open another unit to be known as Prince Cottage, which will be used for men patients only, thus carrying out the original plan of complete segregation.

Chicago

Annual Meeting of Heart Association—Dr. Armin B. Luckhardt, professor of physiology, University of Chicago School of Medicine, will be the guest speaker at the annual meeting of the Chicago Heart Association at Huyler's Restaurant, February 25. His subject will be "Highlights and Shadows in the Discovery of General Anesthesia."

Personal—Dr. Russell D. Harold has been elected secretary-treasurer of the Chicago Urological Society to succeed Dr. Irving J. Shapiro, who has gone into active service with the navy.—Irving B. Fildes, Ph.D., formerly of the National Institute of Health, Bethesda, Md., was recently appointed associate professor of bacteriology at Northwestern University Dental School.

Dr. Kreuscher Retires as Chief Surgeon of Steel Corporation—Dr. Philip Kreuscher, clinical professor of orthopedic surgery at Javal University Medical School from 1919 to 1932 and assistant professor of surgery, Northwestern University Medical School since 1932, has retired as chief surgeon of the Chicago District Carnegie Illinois Steel Corporation, to devote his entire time to his private interests. He had held the position since 1937. Dr. Kreuscher was also medical director for the Industrial Commission of Illinois from 1932 to 1936. He has been succeeded at the steel corporation by Dr. Richard J. Bennett, Jr., who since Jan. 1, 1937, has been associate chief surgeon. Dr. Bennett graduated at Temple University School of Medicine, Philadelphia, in 1927.

Lee Memorial Lecture in Chemistry—Earl Paul Link, Ph.D., professor of biochemistry, University of Wisconsin, Madison, will deliver the Edward C. Lee Memorial Lecture in chemistry in the Kent Chemical Laboratory, University of Chicago, February 25. His address will be entitled "From the Haystack to the Chimney: Commercial Chemistry and Will be an illustrated description of the application of chemistry to a practical problem in agriculture evidencing a new series of 4-hydroxy compounds which alter the coagulability of blood. The lecture was established in honor of Edward C. Lee, Ph.D., an alumnus of the University of Chicago who died shortly after receiving his degree. His wife, who established the lecture in 1940, is an alumna of the university.

INDIANA

Silver Star Awarded to Physician—Capt. William I. Edwards, New Albany army medical corps, now with the American forces somewhere in New Guinea, has been given a Silver Star for heroic action. According to the state medical journal, Captain Edwards was on duty at an American field hospital removing a piece of shrapnel from an Australian soldier when Jap bombers attacked. He continued to operate and when the enemy had gone the patient pointed to a machine gun bullet wound he suffered during the attack and suggested that Captain Edwards perform another operation which he did. The journal stated.

State Board Modifies Regulations—The Indiana State Board of Medical Registration and Examination in January modified some of its regulations in an endeavor to help meet the urgent problems created by the induction of a large number of physicians into the armed forces. Heretofore only one examination has been conducted each year in June but under the revised schedule an examination will be held approximately every eight months permitting recent graduates to enter practice or to enlist in military medical units several months sooner than would have been possible under the single examination a year program which had been in effect since the creation of the board. The board held an examination in

January and the next will be in September. A modified regulation has been announced for the licensing of applicants who are graduates of foreign medical schools providing that the repetition of the senior year's work shall be required of graduates of schools located outside the United States and its possessions excepting for the duration of the present war the possessor of a medical diploma representing the full prescribed medical course in a Canadian medical school recognized by the Indiana state examining board. Previous to the modification, graduates of all schools outside the United States and its territorial possessions were required to repeat their senior year's work in an American medical school before they were eligible to take the Indiana license examination. In a further effort to cooperate with the demands of the emergency the practical examination required of reciprocal applicants from states that require a like examination has been waived for the duration. Under the modification, applicants of other states may be granted reciprocal licensure in about two weeks when practical examinations are not required. With practical examinations it generally had required about three months for an out of state physician to obtain an Indiana license. The requirement of one year of practice in the state from which the applicant reciprocates was also suspended for the duration.

KENTUCKY

Lectures on Tropical Medicine—On January 26 Dr Harold W. Brown, dean of the school of public health University of North Carolina Chapel Hill, and professor of public health at Duke University, Durham, gave two lectures on tropical medicine at the University of Louisville School of Medicine on 'Malaria' and 'Dysentery'. On January 27 Dr M. Ruiz Castaneda of the department of public health of Mexico and professor of the National School of Medicine discussed 'Typhus'. The lectures were made possible by the National Research Council.

State Owned Maternity Hospital Dedicated—The Oneida Hospital for Mothers and Babies of the Mountains was recently dedicated, marking the formal opening of the first maternity hospital in the United States owned by a state and operated by a state department of health. The hospital was opened as the Oneida Mountain Hospital in 1928, but in 1936 Dr C. Adeline McConville, Brooklyn, who established it, offered the building and grounds to the state department of health for use in any way in which it might see fit. In 1941 negotiations were concluded conveying the unit to the commonwealth of Kentucky. Governor Johnson allocated funds to the state department of health for the necessary repairs and improvements and the U. S. Children's Bureau made available an annual appropriation of \$20,000 for its support. The hospital is operated as a unit of the Clay County health department in cooperation with the state department of health and its service program carried out under a plan developed cooperatively by the state department and the U. S. Public Health Service. Patients not able to pay for services are admitted free. Pay patients are charged according to their means with a minimum of 50 cents a day and a maximum of \$2.50 a day for hospital accommodations. Physicians in private practice are permitted to bring their patients to the hospital for delivery and are entitled at all times to the consultation services of the resident obstetrician. Dr Henry H. Caffee, Oneida, is the obstetrician and medical director and the director of the division of maternal and child health of the state department of health serves as maternal and child health supervisor of the hospital. The hospital has been in operation since December 1941. In the last six months it has had a continuing average of 12 patients with a peak load of 21. Principal speakers at the recent dedication included Drs Arthur T. McCormack, Louisville state health officer; Edwin F. Daily, Children's Bureau, U. S. Department of Labor, Washington, D. C. who was instrumental in establishing the project; Governor Johnson and Dr McConville. The *Bulletin* of the state department of health for January was dedicated to a historical review of the undertaking.

MINNESOTA

Chiropractor Loses Basic Science Certificate on Abortion Charge—Henry Wuerzinger, Minneapolis, pleaded guilty at the district court of Hennepin County to practicing medicine without a license. He was sentenced to one year in the county jail but was placed on probation for three years on the condition that he surrender for cancellation his basic science certificate and chiropractic license, turn his medical and surgical equipment over to the Minneapolis General Hospital and return a promissory note in the sum of \$75 to the patient who was the principal in the alleged abortion. Wuerzinger was arrested on Oct. 8, 1942 following an investigation of his activities by the Women's Bureau of the Minneapolis Police Department

and a representative of the Minnesota State Board of Medical Examiners. It was revealed during the investigation that Wuerzinger had performed a criminal operation on a 22-year-old unmarried girl. The patient stated that Wuerzinger charged her \$125 in cash and in addition demanded a promissory note of \$75 dated July 1 and payable in fifteen days. He had been in similar trouble in 1935.

NEBRASKA

Eleventh Annual Assembly Will Be Held—The Omaha Mid West Clinical Society has decided to hold its 1943 assembly at the Hotel Paxton, Omaha, October 25-29.

Personal—Dr. James K. Newman, Omaha, observed his ninety-fourth birthday on January 5.—Dr. Fred P. Deuten, formerly of Rapid City, S. D., has been appointed director of the Hall-Adams Health Unit.

Officers of State Medical Board—Dr. Larle G. John on Grand Island is president of the state board of examiners in medicine, according to an announcement concerning changes in the board. Dr. Ernest T. Manning, Omaha, is vice president and Dr. George W. Covey, Lincoln, secretary.

Society News—The Omaha-Douglas County Medical Society was addressed in Omaha recently by Drs. James Dewey Bigard on 'Surgical Treatment of Esophageal Diverticula', Willis E. Brown on 'Complications with Intrauterine Pessaries' and John L. Gedgoud on 'Virus Pneumonia'.

Serologic Tests of Employees in Industry—The Omaha-Douglas County Medical Society has approved a plan for large scale serologic testing of employees in industry in and around Omaha. When the plans are completed the society will participate by helping to obtain blood from hundreds of employees in the many plants and indirectly wherever possible to submit those of the group whom they know as patients to encourage to the test.

NEW YORK

Graduate Lectures—Dr. Clayton W. Greene, Ithaca, will speak before the Madison County Medical Society in Oneida, February 23, on 'Renal Lesions Simulating Other Maladies'. This lecture is the second of two arranged by Dr. Greene under the auspices of the state medical society as postgraduate instruction on the treatment of common diseases. Dr. I. Maxwell Lockie, Buffalo, gave the first lecture, February 11, on 'The Management of Arthritis, Acute and Chronic'.

New York City

Vesalius Celebration—The section of historical and cultural medicine of the New York Academy of Medicine sponsored a Vesalius Celebration on January 13 to honor the quadricentenary of the publication of 'De Humani Corporis Fabrica' (1543). Papers were delivered by Drs. Arturo Cistighom, Baltimore, on 'Andreas Vesalius, Prof. in the Medical School in Padua' and Henry E. Sigerist, Baltimore, 'The Position of Vesalius in the History of Medicine'. An exhibit of books of Andreas Vesalius from the library of the academy was a feature of the meeting.

Personal—Dr. John L. Rice, formerly city commissioner of health, has been appointed a consultant to Lederle Laboratories.—Miss Max J. H. Rosbach is the new director of child care for the American Women's Voluntary Services in New York.—Dr. Donald D. Van Slyke, of the Rockefeller Institute for Medical Research, department of the hospital has recently been elected an honorary member of the Kungliga Vetenskaps-Societeten (Royal Society of Sciences) of Uppsala, Sweden.—Paul D. Miller, attorney, has been elected president of the Goodwill Industries, a social service organization for the employment and rehabilitation of physically handicapped persons.

New Health Committee for Community Service—Albert G. Milbank, New York, attorney and president of the Milbank Memorial Fund, on February 5 was appointed chairman of a new health committee of the Community Service Society of New York to study the society's program for the control of preventable diseases in New York. The new committee will reexamine the health objectives of the Community Service Society in the light of recently acquired medical and scientific knowledge and initiate steps to adjust the organization's health and medical activities to rapidly changing conditions. Other members of the new committee include Dr. George Baehr, medical director, U. S. Public Health Service Reserve, chief medical officer, Office of Civilian Defense; Dr. Frank G. Bondrean, Charles C. Burlingham, L.L.D., Homer Folks, L.L.D., Dr. James Alexander Miller, Paul B. Barrett and Bayard F. Pope.

Ninth Institute on the Exceptional Child—"The Outlook for the Exceptional Child in Postwar America" is the theme of the ninth Institute on the Exceptional Child to be held at the school of education auditorium, New York University, February 23. The institute is held annually under the auspices of the Child Research Clinic of the Woods Schools, Langhorne, Pa., but this year is being held also in collaboration with the school of education of New York University. Among the speakers will be:

Herbert B. Bruner, Ph.D., The Responsibility of the States to the Exceptional Child
Charlotte E. Grave, Ph.D., Langhorne, The Responsibility of Private Enterprise for the Care of the Exceptional Child in Postwar America
Dr. Irving Edward Liss, The Outlook in Medicine for the Care of the Exceptional Child in Postwar America
Dr. Marion E. Kenworthy, What the Psychiatric Field Can Do for the Exceptional Child in Postwar America
Francis M. Garver, Ph.D., Philadelphia, What is the Outlook in Education for the Exceptional Child in Postwar America?
Mrs. Sidonie Matisner Gruenberg, The Responsibility of the Parent to the Exceptional Child
Dr. George G. Denver, What is the Vocational Outlook for the Exceptional Child in Postwar America?
Edward C. Lindeman, B.S., Creating Public Understanding for Providing Effective Care of Exceptional Children in Postwar America

NORTH CAROLINA

New Academy of Public Health—The North Carolina Academy of Public Health was organized at a recent meeting at the state laboratory of hygiene, Raleigh, according to the *Health Bulletin* of the state board of health. The objectives of the new organization, which is said to be the first of its kind in the United States, are the cultivation of the science of public health, the advancement of the character and honor of the public health profession, the elevation of the standard of education of all public health workers and the promotion of public health and the extension of its benefits to all people. Officers of the new group include Dr. George M. Cooper, Raleigh, assistant state health officer and director of the division of health education, crippled children's work, and maternal and child health service; president, Ernest A. Branch, D.D.S., Raleigh, director of the division of oral hygiene, vice president, and Mrs. Annie B. Edwards, secretary to Dr. Carl V. Reynolds, Raleigh, state health officer, secretary and treasurer. The establishment of the new academy of public health was interesting in view of the recent designation of the North Carolina School of Public Health as a center for training of students in public health education from all parts of the United States in a cooperative program between the W. K. Kellogg Foundation and the United States Public Health Service (*THE JOURNAL*, February 13, p. 525).

OHIO

Medical Officer Cited for Heroic Action—Lieutenant John Robert Schmidt, Cincinnati, M.C., U.S. Naval Reserve, has been cited by the U.S. Navy for heroically carrying out his duties while under fire in the battle of the Midway. According to the state medical journal, Lieutenant Schmidt was also recently mentioned in press dispatches from "somewhere in the South Pacific" for rendering good medical care under adverse conditions aboard a destroyer to survivors of an aircraft carrier sunk by the Japanese.

State Meeting Planned as War Conference—The annual session of the Ohio State Medical Association will be held at the Neil House, Columbus, March 30-31, on the general theme, "Medicine on the Home Front." The afternoon and evening of March 30 will be devoted primarily to business matters and discussions of vital problems arising from the war. A general session will be held the morning of March 31 on "Keeping Them Working," the entire program to be devoted to industrial health. The afternoon session on "Keeping Them Healthy" will cover subjects relating to the health of the civilian population generally under wartime conditions.

Dr. Rollo Baker Named Acting Dean—Rollo C. Baker, Ph.D., secretary of the Ohio State University College of Medicine, Columbus, since 1934, has been named acting dean of the college and acting director of the University Hospital. Dr. Baker was temporarily appointed to fill the position made vacant on January 15 by the death of Dr. Leslie L. Bigelow, Columbus. Dr. Bigelow had also been serving under a temporary appointment while Dr. Hardy A. Kemp, Columbus, is absent on military service. The new acting dean has been continuously associated with the university since he enrolled as a freshman in 1911, except for a short leave while he was working toward his doctor of philosophy degree at the University of Chicago, which he received in 1927. He was born in Middlebourne in 1888. He received the bachelor of arts degree in 1915 at Ohio State University, became a graduate

assistant in that year and continued toward a master's degree which was awarded him in 1917. From 1918 to 1921 he was an instructor in anatomy, in 1921-1928 an assistant professor and in 1928-1932 an associate professor, since 1932 he has been a full professor.

PENNSYLVANIA

Society News—Dr. James M. String, Pittsburgh, discussed "Use of the Newer Insulins" before the Washington County Medical Society in Washington recently. The Reading Eye, Ear, Nose and Throat Society was addressed, January 20, by Dr. Matthew S. Lerner, Philadelphia, on "Deafness: Whose Responsibility Is It? Is It a Lost Cause? Mode of Treatment?"

Philadelphia

College of Pharmacy and Science Begins Accelerated Courses—Consistent with the wartime policy of eliminating summer vacations in a scheduling of the eight semester curriculum leading to bachelor of science, the Philadelphia College of Pharmacy and Science will start its next freshman class on June 28. Assuming that the acceleration policy which is a wartime adjustment will continue operative throughout the eight semesters of the curriculum, the student entering this summer should qualify for graduation in April 1946. For the benefit of the applicants who may qualify for admission this spring and who are desirous of entering on their studies without delay and to complete the curriculum as soon as possible, the college will offer certain freshman courses, namely general chemistry, mathematics (college algebra and trigonometry), German, English composition and mechanical drawing in the spring semester, which begins March 1. These courses will be of collegiate grade and will lead to credits for advanced standing in any one of the four curriculums of pharmacy, chemistry, bacteriology and biology offered by the college.

Annual Report of Hospital Service—The Associated Hospital Service of Philadelphia paid hospitals \$2,361,936.06 or 78 per cent of its earned income in 1942 according to *Philadelphia Medicine*. This figure is an increase from \$1,743,586.20 or 76 per cent paid during 1941. Income from subscription fees came to \$3,007,333.56, an increase from \$2,283,987.93 earned the previous year. Balance added to reserves during 1942 was \$285,095.03 or 95 per cent of income bringing the hospital plan's total reserves against epidemics or other contingencies to about \$1,200,000. The previous year, \$271,470.82 or 11.9 per cent of income, was added to reserves. Operating expenses for 1942 totaled \$370,983.11 or 12 per cent of income as compared with \$257,109.41 or 11 per cent in 1941. At the present time about 450,000 subscribers are enrolled in the service through groups formed in seven thousand business firms and industries. More than 100,000 subscribers have been hospitalized during the four years of operation by the organization. Hospital admissions vary from 100 to 200 subscribers daily and 1800 subscribers are receiving care every day. Newly elected members of the board of directors include Percival I. Loedinger, a trustee of Jefferson Medical College of Philadelphia; Dr. Lucius R. Wilson, medical superintendent of the Hospital of the Protestant Episcopal Church; and Dr. William Bates, president of the Philadelphia County Medical Society.

RHODE ISLAND

Society News—The Providence Medical Association was addressed at its annual meeting, January 4, among others by Drs. Kaler K. Gregory and William A. Horn, Providence, on "Acute Anterior Poliomyelitis—A Review of Essential Features" and "Some Impressions of the Kenny Treatment" respectively. Dr. Meyer Saklad, Providence, addressed the annual meeting of the Memorial Hospital, Pawtucket, November 18, on "Progress in Anesthesia."

Dr. Gormly Honored by Dental Society—Dr. Charles F. Gormly, Providence, was presented with the medal of award and accompanying citation of the Rhode Island State Dental Society on January 27 in acknowledgment of many services to the medical and dental professions. Dr. Gormly is president of the state medical society. The award is given to "one who through eminent service has promoted the advancement of dentistry or furthered its public appreciation."

TENNESSEE

State Meeting Canceled—At a meeting of the board of trustees of the Tennessee State Medical Association it was decided to cancel the annual session planned to be held in Nashville, April 13-15. A meeting of the house of delegates of the association will be called sometime in April the exact dates to be announced later.

WEST VIRGINIA

Personal—Dr William C D McCuskey, Wheeling has been appointed a member of the Public Health Council for the term ending June 30 1945 succeeding Dr Albert H Hoge Bluefield

State Association Will Hold Annual Session—The seventy-sixth annual meeting of the West Virginia State Medical Association will be held at Charleston, May 17-18 with headquarters at the Daniel Boone Hotel Because of war conditions there will be no formal banquet or ball The pre-convention meeting of the council will be held on Sunday evening May 16 and will be followed by the first session of the house of delegates The second session will be held the following day Full scientific programs will be presented during the two day meeting

GENERAL

Meetings Postponed—The medical section of the American Life Convention will not hold its 1943 meeting which was scheduled to be held in June—The annual meeting of the American Urological Association, which was scheduled to be held at the Hotel Jefferson, St Louis, May 31-June 3 has been canceled

Snow Medal Awarded to Dr Wilbur—The William Freeman Snow Medal for distinguished service to humanity was awarded to Dr Ray Lyman Wilbur, chancellor of Stanford University Calif during the annual dinner meeting of the American Social Hygiene Association February 1 The medal was awarded to Dr Wilbur "in recognition of the outstanding work he has done to protect American youth from the ravages of social disease" Dr Wilbur has been president of the American Social Hygiene Association since 1936

New Publication on Dentistry—Dr Carl W Waldron Minneapolis has been named editor of the new *Journal of Oral Surgery* to be published by the American Dental Association and L Pierce Anthony, DDS, editor of the *Journal of the American Dental Association* has been named editor in chief Dr Waldron graduated at the University of Toronto Faculty of Medicine in 1911 He received his degree in dentistry at the Royal College of Dental Surgeons in 1913 He has been serving at the University of Minnesota School of Dentistry, Minneapolis, as professor of oral surgery and as professional lecturer in the school of medicine

Hospital Association Creates Service Bureau—The American Hospital Association has established a wartime service bureau and named Mr James Russell Clark, Bay Shore, N Y, as director The service bureau is the result of action by the house of delegates of the association at its 1942 meeting in St Louis, October 12-16 It will have headquarters in Washington and was expected to be in operation February 15 The wartime service bureau will be under the supervision of the council on government relations of the association, which Mr Clark will also serve as secretary Mr Clark has for the past seven years been administering the Southside Hospital in Bay Shore The new bureau is for service to the association and the hospital field in general and not to promote legislation

Method for Determination of Cadmium—*Industrial Hygiene* reports that a dithizone method for the determination of cadmium has been worked out by Alfred N Setterlund, MS, and Arthur H Krause, BS, Chicago of the Illinois Division of Industrial Hygiene The method is especially applicable to air samples Accurate results may be obtained even in the presence of large quantities of other metals such as zinc, lead and copper Description of the procedure may be obtained in mimeographed form from the Division of Industrial Hygiene Illinois State Department of Public Health 1800 West Tillmore Street Chicago

Dr Lela Booher Appointed Chief Nutritionist at General Mills—Lela E Booher, PhD, director of Institute of Nutrition at the Milwaukee Children's Hospital Milwaukee has been appointed chief nutritionist of General Mills Inc, Minneapolis Dr Booher received her PhD degree at Columbia University New York in 1928 She subsequently served as instructor in biochemistry at New York Post-Graduate Medical School research assistant in chemistry at Columbia University, and biochemist at St Lukes Hospital, Cleveland, returning to Columbia as instructor in chemistry where she served from 1930 to 1936 She was chief of foods and nutrition Bureau of Home Economics U S Department of Agriculture, from 1936 to 1941 In 1938 she represented the United States at the Geneva Conference on Nutrition at the League of Nations

Tips to Save Rubber—The Bureau of Home Economics, Research Administration, U S Department of Agriculture has recently issued a folder and a set of printed posters to help

in the conservation of rubber 'Take Care of Household Rubber' is the title of the pamphlet which tells in popular style how to make rubber last by right storage by removing spots and by mending with a cold patch or hot patch when a first break appears Single copies of the folder are available free on request from the Office of Information U S Department of Agriculture Washington D C Make Your Rubber Last is the title and theme of the five printed posters which pictorially describe the story of care and repair The posters, 14½ by 20 inches in size are designed for use in class instruction or group meetings They are available from the Superintendent of Documents Government Printing Office Washington D C at 10 cents a set The set is especially helpful to nurses and others who handle supplies for the sick

Special Society Elections—Dr E Bishop Mumford Indianapolis was named president-elect of the American Academy of Orthopaedic Surgeons at its annual meeting in Chicago on January 17-20 and Dr Marius N Smith Petersen Boston was installed as president Other officers are Drs Fremont A Chandler Chicago treasurer Arthur G Davis Erie Pa vice president Myron O Henry Minneapolis secretary and Edward L Compere Chicago librarian historian—Dr C Lydon Harrell, Norfolk Va, was elected president of the Seaboard Medical Association at its annual meeting in Wilson N C, Dec 1-3, 1942 Vice presidents are Drs Malory A Pittman, Wilson, Horace G Ashburn Norfolk Thomas I Lee, Kingston N C and Oscar R Yates Suffolk Va Dr Clarence P Jones, Newport News Va, was reelected secretary-treasurer The forty-eighth annual meeting of the association will be held at the Hotel Jefferson, Richmond Va, November 30-December 2—Dr Frederic Wertham New York was chosen president of the Association for the Advancement of Psychotherapy at its recent annual meeting Dr Joseph Wilder New York vice president and Dr Emilian A Gutheil New York, secretary Dr Franz M Groedel New York addressed the meeting on "Psychosomatic Relationships in Heart Disease"

Willard Gibbs Medal Awarded to Dr Elvehjem—The Chicago Section of the American Chemical Society has awarded its thirty-second Willard Gibbs Medal to Conrad A Elvehjem PhD, professor of biochemistry, University of Wisconsin Madison, according to the *Chemical Bulletin* The medal will be presented formally to Dr Elvehjem during the meeting of the Chicago Section May 20 The medal founded by the late William A Converse, is given in special recognition of eminent work in and original contributions to pure or applied chemistry Dr Elvehjem was born in McFarland Wis in 1901 and received his degree of doctor of philosophy at the University of Wisconsin in 1927 He has been a member of the faculty of the university since 1925, when he became instructor in biochemistry He became assistant professor in 1930 after a year of study at Cambridge University, England, associate professor in 1932 and professor in 1936 He has been a member of the Council on Foods and Nutrition of the American Medical Association since 1942 Dr Elvehjem was awarded the Gibbs Medal for his studies involving trace elements in nutrition, tissue respiration, B vitamins miscellaneous studies in nicotinic acid studies demonstrating that chick dermatitis is due to pantothenic acid deficiency and for studies on the newer members of the vitamin B complex now in progress

Increase in Catastrophe Fatalities—The *Statistical Bulletin* of the Metropolitan Life Insurance Company reports that the number of deaths occurring in catastrophes in 1942 totaled approximately 2600, more than two and one half times as many deaths as in 1941 catastrophes The bulletin explains that catastrophes have been designated as those disasters in which the toll is at least 5 lives In 1941 the largest single accident accounted for 37 deaths In 1942 the most tragic accident was the Boston night club fire, in which 488 were killed Two coal mine explosions, one in West Virginia and the other in Colorado, took 56 and 34 lives respectively There were 54 victims in an explosion at an ordnance plant in Illinois Close to 50 persons died when sodium fluoride mistaken for powdered milk, was used in the preparation of food at a mental disease hospital in Oregon A double disaster, the sinking of a tanker and a barge on Lake Erie, took 32 lives The premature explosion of tons of gelatinite at a quarry in Pennsylvania killed 31 men Tornadoes claimed more lives in 1942 than in any of the preceding five years Most disastrous were the tornadoes which took a toll of 111 lives in seven Southern and Midwestern states in March Three series of tornadoes killed more than 100 persons in Oklahoma during the months of April to June It is interesting to note, the bulletin states, that there were many serious catastrophes in 1917 also An explosion in a Pennsylvania munitions plant in April 1917 took 112 lives A copper mine

fire in Montana and coal mine explosions in Colorado and Kentucky took 163, 121 and 62 lives respectively. There were a series of tornadoes toward the end of May of that year which killed 300 persons.

Noise Abatement Council Announces Achievement Awards for 1943—Announcement is made of the National Noise Abatement Council Achievement Award competition for 1943. Four awards for outstanding achievement in the elimination of needless noise will be made this year, one in each of four city population groups as follows: group 1 cities of over 500,000 population; group 2 cities of 250,000 to 500,000 population; group 3 cities of 100,000 to 250,000 population; and group 4 cities of less than 100,000 population. The awards will be given to the city in each group submitting on or before July 1, 1943, the most conclusive evidence of outstanding accomplishment during the period June 7, 1942, to June 5, 1943, in the abatement of unnecessary street noise and the control of industrial office and in-the-house noises and in the observance of National Noise Abatement Week, May 30 to June 5, 1943. Emphasized in the council's 1943 antinoise campaign and especially sought in this year's achievement award competition will be evidence of noise abatement activities directed toward the elimination of industrial office and in-the-house noises as a civilian health and welfare measure for the conservation of manpower and to aid war production. The plaque that will be given to each of the winners executed by Rene Paul Chamebelle, sculptor, New York, symbolizes the war that is being waged against needless noise. The plaque depicts Aeneas, Trojan warrior hero of Virgil's "Aeneid," overcoming the many-headed monster Cerberus who guarded the gates to Hades. Aeneas, who had gone there seeking counsel from his father, Anchises, as to the future fortunes of his race, is portrayed in the act of hurling bits of drugged food into the jaws of the beast. Thus, according to Virgil's tale, effectively quells Cerberus, who falls asleep. Material submitted as supporting evidence to claims for the awards must be received by the National Noise Abatement Council not later than July 1, 1943, and may consist of any or all of the following:

Newspaper Clipping—New stories, photographs, cartoons, features and editorials.
Photographs—Of civic and special activities and window and store display.
Scripts—Of radio announcements and program, other talks and lecture.
Official Statements—Photostat or other copy of proclamations and statement issued.
Posters—Car Card—Samples or photographs with the number and method of distribution.
Record of Events—Date, name and place—where and when events occurred.
Statement of Result—Official comment, facts and traffic record, other testimonials.
Miscellaneous—Any other material or evidence of a supporting nature.

Entries may be made by any city official or department, chamber of commerce, noise abatement committee or council or by any other representative civic group or organization. Material submitted cannot be returned and will become the property of the National Noise Abatement Council. The decisions of the National Noise Abatement Council's Committee on Awards will be final. Address entries to Committee on Awards, National Noise Abatement Council, 9 Rockefeller Plaza, New York.

Annual Report of the Commonwealth Fund—According to its twenty-fourth annual report, the Commonwealth Fund expended \$1,937,224 during the year ended Sept. 30, 1942. Of the total, \$416,500 went to war relief, \$343,788 to medical research, \$63,648 to medical education, \$462,203 to rural hospitals, \$236,684 to public health, \$21,678 to health studies, \$117,044 to mental hygiene and \$16,731 to mental hygiene in England. A total of \$58,750 was used for research on problems of war medicine. A third of the undertakings aided during the year have a bearing on specific issues of war medicine. A new grant of \$4,500 to the Long Island College of Medicine enabled the college to invite visiting instructors to participate in its teaching program. Dr. Thomas Addis, professor of medicine at Stanford University School of Medicine, San Francisco, stayed for a six-week period and members of the Cornell University Medical College assisted in the work in parasitology.

The report reviews the fund's help to projects in this country and England, pointing out that the Child Guidance Council had returned to London from its temporary quarters at Bath, Kay County, Okla., was selected for a second demonstration of county health department activities. Seminole County will receive assistance until July. Support for health department activities was discontinued in Jones County, Miss., and Sumner County, Tenn., and no further demonstrations of this type are contemplated for these states. The experimental subsidy to the East Alabama Health District, in which there was an

advisory staff of specialists for an entire district, ended following the death of Dr. James N. Baker, on whose initiative the plan was launched. An increase was noted of about 8 per cent in the occupancy of the thirteen rural hospitals in eleven states assisted by the fund.

The last three of the fund's fellowships for British students terminated at the end of the last academic year, no further appointments will be made for the duration of the war. However, the fund offered a new group of fellowships to physicians, sanitary officers, technicians or public health nurses chosen in cooperation with medical and health authorities of the Latin American nations and with the advice and assistance of the Pan American Sanitary Bureau. Fifteen of these fellowships went to representatives of Argentina, Brazil, Chile, Costa Rica, Cuba, Guatemala, Honduras, Paraguay and Peru.

A plan to expand the psychiatric service in the department of medicine at the Peter Bent Brigham Hospital, Boston, was discontinued on the death of Dr. Soma Weiss, physician in chief at the hospital and the resignation of Dr. John Romano, the psychiatrist, to become professor of psychiatry at the University of Cincinnati School of Medicine. Additional internships were established at the Payne Whitney Psychiatric Clinic of the New York Hospital to supplement similar assistance at the Henry Phipps Psychiatric Clinic at Johns Hopkins University and the Colorado Psychopathic Hospital. Noteworthy contributions to the bacteriologic control of communicable disease likely to be prevalent in armies have been made through the study of bacterial nutritive requirements at Harvard and the epidemiologic study of poliomyelitis there helped to win general medical support for one preventive measure—the postponement of tonsillectomies beyond the season when paralytic poliomyelitis is most common. At New York Hospital an analysis of hereditary factors in the incidence of rheumatic fever reached the conclusion that the disease follows a predictable pattern of genetic susceptibility.

CANADA

Honor Memory of Sir Frederick Banting—The chancellor and president of the University of Toronto and members of the university staff accompanied Lady Banting to Mount Pleasant Cemetery recently to place a wreath on Sir Frederick's tomb. The occasion marked the fifty-first birthday anniversary of Sir Frederick, co-discoverer of insulin. The *Canadian Medical Association Journal* reports that this may become an annual ceremony.

Changes in Faculty at University of Alberta—Dr. John Ross Vant has been named head of the department of obstetrics and gynecology at the University of Alberta Faculty of Medicine, Edmonton, and Dr. Herman O. Baker has been named professor in the department. The announcement that appeared in *The Journal*, Dec. 19, 1942, page 1329, and listed Dr. Vant as professor of obstetrics and gynecology and Dr. Baker as associate professor was taken from the *Canadian Medical Association Journal*, November 1942, page 492.

FOREIGN

Planning for Science—The Association of Scientific Workers in Great Britain organized a conference held on January 30 and 31 on the planning of science in war and peace. Consideration was given to plans of the United States of America and of Russia for the organization of research in the war and postwar periods. Special attention was given also to reconcentration of science after the war.

Government Services

Dr. Dyer Heads New Committee for Typhus and Rickettsial Diseases

Dr. Rolla E. Dyer, assistant director of the National Institute of Health, Bethesda, Md., has accepted the chairmanhip of a committee of the Pan American Sanitary Bureau for study of typhus and rickettsial diseases. According to *Military Surgeon*, creation of this committee was recommended at the eleventh Pan American Sanitary Conference held at Rio de Janeiro, Brazil, Sept. 7-18, 1942. The particular purpose is to determine the different varieties of typhus virus existing in each country with a view of obtaining better resources for vaccination to study the reservoirs and vectors of virus in each country and to submit the conclusions of these studies to the proper conference.

Elaborate New System for the Treatment of Injuries

The Emergency Hospital Service, referred to from time to time in previous letters to THE JOURNAL, was originally intended for the treatment of casualties from air raids and other work in connection with the war. It has now a much larger scope. It has established a large scale orthopedic and fracture treatment service with facilities for rehabilitation. Manual workers in "war industry"—a term widely interpreted to include munition work, shipbuilding and repairing, building and civil engineering, mining, agriculture, fishing, public utility undertakings, shipping and transport—are entitled to treatment. The injury need not have been suffered during employment. This new service is maintained by a series of graded hospitals. In England and Wales there are twenty-one orthopedic centers for complicated cases, sixty fracture departments for cases less complicated but requiring long treatment, two hundred hospitals for short stay cases and fracture clinics for follow-up treatment. The orthopedic centers provide the full continuity of treatment and rehabilitation service including all aspects of specialist treatment from the original resetting of the injury, through physical therapy and remedial exercises and games to complete occupational therapy.

The fracture departments are divided into two classes. Fracture departments of the A class are similar in conception to the orthopedic centers and deal with long stay cases and rehabilitation, but differ in not handling the more complicated cases, which are transferred to those centers and in not including full work shop occupation, though providing occupational therapy of a handicraft type and covering all ordinary massage, exercise and physical therapy. They also provide for full continuity of specialist treatment. Hospitals suited by specialist service and equipment to cooperate in the fracture service are classified as B because their situation in areas vulnerable to air attack is unsuited to the smooth treatment of long stay cases. They are used for short stay cases or ambulant cases.

Provision is made for follow-up treatment after the patient's discharge from the hospital. Orthopedic centers and fracture departments have outpatient services where after-care massage and physical therapy are provided. To fill up gaps and enable service to be given nearer home where possible, use is made of a number of selected clinics and hospitals able to give suitable service on the prescription of the surgeon who originally attended the injury.

Claim of Women for Compensation

Attacks from the air on this country have resulted in a large number of civilian casualties, for which the government pays compensation. In the House of Commons Mrs. Tate moved an amendment to the address expressing regret that the same rate of compensation was not paid to women as to men. These pensions were paid from taxation, to which women paid at the same rate as men. Replying for the government Mr. Attlee said that the appeal for equal compensation for civilian war injuries was a strong one. It was based on the principle of equal injury but in this country we had a system based on a different principle, namely the earnings of injured persons. Workmen's compensation was based on this. Compensation for civil defense workers, including compensation for accidents on duty, would ordinarily come under workers' compensation. In practice payments were made to men and women in civil defense

on the basis of a maximum of six months' whole time pay. In the services the pay of men and women was different and the compensation differed accordingly. Compensation was not given as an injury allowance; there was a pension for total disability. For civil defense workers and for the uniformed services pensions were the same in the basic grades but differed for men and women. If it was proposed that civil defense workers should be given equality as between the sexes the same would have to be done for the armed forces. A change of such magnitude should not be taken on one afternoon's debate in the House. The government proposed that a select committee should be set up to report on the proposal that civilian women should be compensated equally with civilian men for war injuries on the general principles of compensation and on the levels of remuneration. The question could not be settled on an abstract principle.

In the debate which followed support and opposition did not follow party lines but cut across them. A point was made of the great services rendered by women in this war, which far surpassed those of the last war. The amendment was negatived by 229 votes to 95.

American Blinded Soldiers to Be Cared for in St. Dunstan's

At a luncheon given by St. Dunstan's Institute for fighting men blinded in the war the principal guests were Brigadier General Hawley, chief surgeon of the Army of the United States in the European theater of operations and Brigadier R. M. Luton, director of medical services, Canadian military headquarters. Mr. Ernest Brown, minister of health, said that in the field of medicine and surgery a happy comradeship between the English speaking allies had developed since the war began. The most recent example of Anglo-American cooperation was that St. Dunstan's had just concluded an arrangement under which American soldiers blinded in the war would be cared for in St. Dunstan's Hospital and Training Center while awaiting evacuation and British casualties across the Atlantic would be similarly treated by the Americans. In the early days of the war American doctors came at their own expense and without remuneration to help in our hospitals. When American forces began to reach this country we arranged that they as well as other American nationals needing treatment should be accommodated in our emergency hospitals. In addition the Ministry of Health had handed over to the Americans five new fully equipped hospitals.

Age for Calling Up Recruits Lowered

The calling up age of young men for the army has been lowered from 18 years to 17 years and 6 months. But the age of liability for military service remains the same 18 years and also the youngest age for sending men overseas which is 19 years. The object is to provide a longer period of training. The government endeavored to postpone the date of calling up young persons of the minimum age as long as possible, but the manpower situation compelled this new measure. It is held that this war cannot be won with a mass produced army, individual action by the soldier is necessary. It is therefore an advantage to give recruits the longest possible training in this country before they are sent overseas and to make them fit for the strenuous battles they will be called on to face.

The Importance of Preventive Medicine

Addressing the Congress of the British Medical Students Association Mr. Ernest Brown, minister of health, said that the air was full of new ideas and new trends but that there was one we should keep constantly in front of us—preventive medicine and positive health. The age long function of the physician was to cure and relieve the sick. But it was right

that the minister of health (not minister of disease) should insist on a second duty—to prevent disease and point the way to positive health. In this second battle the doctors of the future would not be alone. They would form part of a great army of workers—nurses, teachers, engineers and architects—who were anxious to prevent disease and took for their motto "Prevention is better than cure." In their clinical work his audience would try to make a diagnosis at the earliest possible stage and to push back the diagnosis until the first tiny flowering of disease could be detected and nipped in the bud. If they carried this a stage further they would find themselves preventing disease before it had shown itself. Perhaps the greatest handicap in the practice of preventive medicine today is not that we do not know how to prevent many diseases but that the public does not take full advantage of the knowledge we have. A "doctor" originally meant a teacher. We looked to doctors to teach and lead the public so that valuable lives were not lost through ignorance of the means of prevention.

Child Mortality in Egypt

From reports of the Research committee organized by the Egyptian Health Department to investigate child mortality rates, it is learned that the average annual births for the last few years have been approximately 650,000 and deaths 430,000, 240,000 of the latter being of children 110,000 babies under 1 year and 130,000 from 1 to 5 years old. One third of the newborn babies of Egypt die, therefore, before reaching the age of 5, while half of this number die during their first year. This high incidence of mortality tells a sad story of a diseased and suffering childhood.

The average death rates per thousand births are

In the Years	Urban	Rural	The Whole Country
1921-1925	261	130	144
1926-1930	217	138	152
1931-1935	207	147	165
1936	205	150	164
1937	206	149	165

as compared with Austria 81, India 162, Belgium 80, Bulgaria 150, Germany 64, Italy 100, England 58, and Japan 106 in 1937.

The incidence of mortality in rural communities has been growing with the years. The high figures are partly due to the increasing registration of deaths in the villages since the habit of secret interment has decreased, but there may be also an actual increase in the number of deaths owing to the low social and economic standard of the peasantry.

The incidence of child mortality in Egypt has been much higher than in many poorer countries that have a lower cultural standard. These high death rates are caused primarily by hunger, deprivation, ignorance, uninstructed motherhood and too great a number of births especially among destitute families, the results of which are malnutrition, poor housing accommodation, hard labor for women resulting in the deterioration of the body, mind and lung defects, diseases of the stomach and hereditary diseases. To this must be added the ignorance of the midwives and the few maternity and child welfare institutions.

The falling in the number of cases of infant mortality in the cities during the 1936-1940 period was to some extent due to improvement in the general health conditions of the city population and the establishment of infant welfare stations.

Welfare of Children in Wartime

The medical institution of Hadassah is conducting a network of school luncheons throughout the country. This work was first started in 1923 but in the last few years has developed with great strides. Through these school luncheons the hungry and needy children, selected by the school nurse in the schools and kindergartens subsidized, are given one nourishing meal a day. The meal, which costs 12 mils (5 cents), contains three dishes and is planned in such a way as to provide from 30 to 40 per cent of the daily food requirement of a child 10 years of age.

In seventy-eight of these schools the work is done on an educational basis, i.e., a cooking teacher gives instruction in cooking to rotating groups of 8 to 10 pupils, who under her guidance prepare a daily luncheon for between 150 and 300 of the neediest of their fellow pupils. The cooking teacher also gives instruction in nutrition in the classroom to the seventh and eighth grade pupils. In the year 1940-1941 this work was conducted in 5 towns and 47 settlements in Palestine. There also exists a central kitchen in each of the two main towns (Jerusalem and Tel Aviv) sending out 3,000 and 1,200 meals respectively to different schools. From school kitchens where cooking teachers are employed meals are also sent out to neighboring schools without cooking teachers. In this way a total of 248 schools (of which 78 were with cooking teachers) and 52 kindergartens were reached.

The number of children fed in all these institutions was 25,385 and the total number of workers engaged in the project was 308. The total yearly budget involved was nearly £75,000, of which about £25,000 was contributed by Hadassah, the Women's Zionist Organization of America and £10,000 by the General Council (Va'ad Leumi) of the Jewish Community of Palestine out of the government grant while the remaining budget of about £40,000 was covered by contributions of the Tel-Aviv municipality, local councils, local feeding committees and parents' committees, as well as by children's payments for meals.

Vaccination Against Jericho Boil (Aleppo Boil)

The Palestine Potash Company Limited, and Kupat Holim (Palestine Jewish Workmen's Sick Fund) have worked long in their search for means of combating the Jericho boil. Thanks to the keen interest and assistance given by Professor Adler of the Hebrew University a vaccine has been provided and all the workers of the potash plant have been inoculated by the Kupat Holim physician Dr. Katzenellenbogen. The results of this inoculation were described by Dr. Katzenellenbogen in the 1942 issue of the Hebrew medical journal *Harefu*.

It was decided to inoculate a number of noninfected recent arrivals and noninfected residents with living virus. Material used for inoculation consisted both of cultures of *Leishmania tropica* on Loeffler-serum agar isolated from a local case and *Leishman-Donovan* bodies of the same strain from the spleens of infected Syrian hamsters. The animals were infected by inoculating cultures directly into the spleen as described by Adler and Ashbel (*Ann Trop Med* 34:207 [Dec] 1940). Inoculations were made on the anterior surface of the thigh about 10 cm above the knee, 0.2 cc in the case of culture and 0.05 cc of emulsion in the case of *Leishman-Donovan* bodies were injected intradermally. A total of 167 persons were inoculated, 82 with *Leishman-Donovan* bodies and 85 with cultures, 152 cases were observed for a period of six to ten months.

The incubation period varied from less than two weeks to more than two months. In 7 cases lesions appeared both on the site of inoculation and on remote sites (the neck, face and arms) and it is believed that in these cases the inoculation

was made during the incubation period of natural infection. Reinfection succeeded in 1 case out of 13 tested. With the exception of the 7 cases in which inoculation was done during the inoculation period of natural infection none of the incubated cases showed any lesion apart from the experimental sore on the left thigh. Twenty cases were tested by intradermal inoculation of 100 000 dead flagellates shortly after Leishman-Donovan bodies were found in the experimental lesions. In 18 a positive reaction was observed within forty-eight hours. Ten cases were similarly tested during the incubation period and in all of them the reaction was negative. The effects of vaccination are indisputable, and all persons entering hyperendemic centers and noninfected residents should be vaccinated preferably shortly after the termination of the sandfly season. The inoculation of some persons during the incubation period of a natural infection is inevitable, but they are none the worse for an additional sore in an unexposed part and all other persons are spared unsightly scars in exposed parts. It was also noted that Leishman-Donovan bodies from the spleens of infected hamsters produced only local cutaneous lesions in human beings without any evidence of visceral involvement.

Inoculation of Killed BCG Vaccine for the Early Diagnosis of Tuberculosis in Infants

As previously reported in *THE JOURNAL*, Dr Alindo de Assis of the Viscondessa de Moraes Tuberculosis Institute of Rio de Janeiro has been carrying out extensive studies on the pathogenicity of the BCG vaccine and on the human conditions described by Saye, Saenz, Sayago and others as "infratuberculin allergy," a state closely related to the so called latent allergy of tuberculous guinea pigs, after Willis. These scientific investigations promise to have practical significance in the near future. In a paper in collaboration with Dr Alvimar de Carvalho of the same institute (*THE JOURNAL* Nov 28, 1942, p 1053) Dr de Assis reported his attempts to establish the foundation of a standard technique to ascertain the condition of infratuberculin allergy in man. He pointed out the behavior of the skin of normal children, i.e. without tuberculosis when inoculated with 0.1 mg of BCG vaccine killed by heating at 65 C. In a new paper Dr de Assis gives an account of the results of the study of the apparently anallergic reactions in 8 children, as they did not react at first to the highest dose of tuberculin (10 mg) intradermally. Nevertheless, further observation of the patients demonstrated that in reality they all harbored virulent tubercle bacilli at the time they first were tested with tuberculin. In all these children the classic allergy was in course of preparation, but the use of the killed BCG vaccine had as a consequence the disclosure of this preparatory condition, rapidly going over all the stages of the so called preallergic period and immediately betraying the existence of a virulent infection. The new work of Dr de Assis is quite different from several contributions previously reported in the medical literature because it has the essential character of revealing the initial stages of the allergic impregnation during the course of the tuberculous infection, and not the mere disclosure of the residual vestiges of an extinguished infection.

The 8 children, whose ages varied from 1 to 7 years, were first submitted to the tuberculin diagnostic test and found anallergic and then received intradermally 0.1 mg of killed BCG vaccine. During the subsequent period they were carefully studied by means of clinical bacteriologic, radiographic and allergic examinations. Contrary to what happens in non-tuberculosis infected children Dr de Assis's patients showed precocious and intense nodular reactions at the place of the

BCG inoculations. During the first two weeks all these nodular foci had a diameter of more than 5 mm and some of them also at this early stage presented cessation. In 3 of the cases the nodular reactions were related to the tuberculin type considerably increasing during forty-eight to ninety-six hours then decreasing and later increasing again. Moreover in 4 cases postvaccinal tuberculin allergy appeared within eight days, as characterizes the Willis-Save phenomenon. In 4 of the remaining cases this tuberculin veering occurred late, but its features of intensity and duration together with other factors for the study of each case were sufficient to prove that the interpretation had to be the same as in the other 4 cases. As in individuals in early infancy without any history of manifest tuberculous disease or history of BCG immunization the nodular and tuberculin Willis-Save reactions have been considered as revealing virulent tuberculosis eventually in the preallergic period. In 4 cases the inoculation of the gastric washings in guinea pigs has proved that the hypothesis was correct. In the remaining 4 the study of the successive roentgenograms the clinical symptoms and the home investigations as well as the features of tuberculin allergy, proved also that the existence of virulent tuberculous infection was practically a certainty.

In conclusion, Dr de Assis's work proves that during the course of the tuberculosis primary infection of infancy, the tuberculin allergy of the skin is established progressively through a preallergic period the presence of which had not previously been demonstrated. The intradermal inoculation of dead bodies of the tubercle bacillus (0.1 mg of BCG vaccine killed by heating) in children who are in the preallergic period is accompanied by specific and characteristic reactions that permit the recognition of the preexistence of a virulent tuberculous infection before the appearance of cutaneous allergy and consequently of the x-ray signs and the local and general clinical symptoms.

Association of Thiamine and Riboflavin to Stimulate Growth

Dr Moura Campos, professor of physiology at the University of São Paulo is carrying out a series of investigations on the vitamin content of Brazilian foods and on the practical importance of the different vitamins. In a recent paper he reported his work showing that thiamine and riboflavin act in association to help in the utilization of the food material by stimulation of the appetite and increase of the food assimilation. Dr Campos's experiments have shown that the presence of thiamine is necessary to the utilization of riboflavin. Thiamine alone cannot maintain the growing capacity. *Mandioquinha* (*Chaerophyllum bulbosum*) has riboflavin but does not contain thiamine. *Goiaba* (*Psidium guajava*) presents both thiamine and riboflavin. These foodstuffs produced clear positive and negative results in the experiments the growth of the rats being maintained well when the animals were fed on the latter fruit alone.

Marriages

JULIAN PATTERSON HARDY Newala, Ala, to Miss Marion Frances Doughty of Tuscaloosa recently.

ORVILLE PATTON STONE to Miss Hazel Louise Woodcock both of New Orleans December 18.

ROBERT DEWEY SANDERS Victoria, Texas, to Miss Helen Mathias in Houston February 6.

VINCENT I THACKER Dothan, Ala, to Miss Nettie M Smith of Troy, November 24.

FRANK J CERNY Berwyn, Ill, to Miss Viola McNeel in Chicago, November 8.

DALF A ROLD to Miss Mary Louise Stropes, both of Chicago, December 23.

Deaths

Hermann Johannes Boldt * White Plains N. Y., University of the City of New York Medical Department, New York, 1879, formerly a pharmacist, emeritus professor of gynecology at the New York Post-Graduate Medical School, where he had been professor of gynecology from 1891 to 1917, consulting gynecologist to the New York Post-Graduate Medical School and Hospital, Stuyvesant Polyclinic, St. Vincent's, Beth Israel and Union hospitals, member of the Southern Surgical Association, one of the founders, formerly a member of the board of governors and fellow of the American College of Surgeons, honorary member of the American Gynecological Society, the American Gynecologic Club, Gynecological Society of Great Britain and the Westchester Surgical Society, member of the National Society of Sciences, New York Academy of Sciences, Association of Military Surgeons of the United States, New York Academy of Medicine and Royal Society of Medicine, London, extensive investigator into physiologic action of cocaine and gynecologic pathology, inventor of an operating table for abdominal surgery which won a medal at the Paris exposition in 1900 and also a modern examining table for office work, aged 86, died accidentally, January 12, in a hotel at St. Petersburg, Fla., of fumes from a small heater.

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States
Department of Agriculture

[EDITORIAL NOTE—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act and in cases in which they refer to drugs and devices they are designated D D N J and foods, F N J. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Black Tablets for Kidneys Bladder and Ureters—W H Goebel trading as Botanical Medicine Company, Kansaspolis N C. Shipped between June 7 and 10 1940. Composition: compounds of magnesium and aluminum cubes coprolin methyl salicylate and sugar. Misbranded because falsely represented on label to be efficacious for the conditions suggested by the name of the product whereas they were not.—[D D N J F D C 426 September 1942]

Calawbas Bu Q Ju Diurelle—W H Goebel trading as Botanical Medicine Company, Kansaspolis N C. Shipped between June 7 and 10 1940. Composition: essentially sugar alcohol and water with extracts of plant drugs including cubebs and peppermint. Misbranded because claim on label aids the elimination of the toxic poisonous substances was false and misleading.—[D D N J F D C 426 September 1942]

Catawbas Pep A Man Tonic Laxative—W H Goebel trading as Botanical Medicine Company, Kansaspolis N C. Shipped between June 7 and 10 1940. Composition: extracts of plant drugs including a laxative drug alone and strychnine sulfate. Misbranded because of false and misleading representations on the label that it possessed tonic properties and the restorative vitalizing and invigorating properties implied in the name. Pep A Man.—[D D N J F D C 426 September 1942]

Digesto Pep—Smith Brothers Drug Company, Greenboro N C. Shipped Dec 10 1940. Composition: alkaline compounds including a laxative compound and digestive. Misbranded because its name and the terms used such as aids digestion and intended for use in correcting conditions associated with sluggish digestion were false and misleading since the product was not a digestant of the various constituents of food could not be depended on to produce pep or aid digestion and correct sluggish digestions. Further misbranded because label statements keep in step with Digesto Pep and so smiling, thru thousands do were false and misleading, since the product could not be depended on to fulfill the implied promises.—[D D A J F D C 446 September 1942]

Pine Orum Compound—John C Schaffer trading as Pine Orum Chemical Company, New Augusta Miss. Shipped Feb 23 1940. Composition: a medium heavy oil with a strong pine oil odor consisting essentially of a pine tar distillate containing sulfur or sulfur compounds and a small amount of water. Misbranded because of false and misleading statements on bottle label representing that the product was an efficacious treatment for coughs colds pneumonia headache indigestion worms burns infections blood poisoning tonsillitis pyorrhea rheumatism old chronic sores athlete's foot hemorrhoids and dandruff among other things would stop the flow of blood and when used in the bath would have medicinal properties. Further misbranded because package did not conspicuously show name and place of business of manufacturer, packer or distributor nor did label accurately state quantity of contents or common or usual name of each active ingredient or give directions for external use for which it was intended.—[D D N J F D C 439 September 1942]

Vitaphore—Vitaphore Appliances Inc. South Bend Ind. Shipped April 27 1940. Composition: an electrical device so constructed as to apply vibration and heat to the body. Falsely represented to improve the complexion rebuild health rejuvenate remedy headaches neuritis scars skin diseases varicose veins asthma catarrh falling hair pyorrhea female disorders and a good many other things.—[D D N J F D C 393 March 1942]

Vitaphosphates—Physicians Drug and Supply Company, Philadelphia. Shipped between April 16 and 30 1940. Composition: less than 50 U S P units of vitamin B₁ per fluid ounce whereas label falsely represented a content of 400 U S P units of this vitamin per fluid ounce hence adulterated and misbranded.—[D D N J F D C 462 September 1942]

Youngs (Dr) Pilonment—F E Young and Company, Chicago. Shipped between May 10 and June 10 1940. Composition: essentially petrolatum (99.15 per cent) with phenol (0.73 per cent) and extracts of drugs including a mydriatic drug such as belladonna. Misbranded because falsely represented on label to promote healing of hemorrhoids and in conjunction with Dr Youngs Rectal Dilators (which were declared misbranded in this same case) to be an effective treatment for rectal irritation and itching and bleeding hemorrhoids.—[D D N J F D C 335 March 1942]

Oklahoma Reciprocity Report

The Oklahoma State Board of Medical Examiners reports 19 physicians licensed to practice medicine by reciprocity and 1 physician so licensed on endorsement of credentials of the National Board of Medical Examiners from June 8 through Dec 31, 1942 The following schools were represented

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Northwestern University Medical School	(1942)		Kansas
State University of Iowa College of Medicine (1914) (1925)	(1905)		Iowa
University of Kansas School of Medicine	(1930)		Kansas
University of Louisville School of Medicine (1940)	(1941)		Kentucky
Tulane University of Louisiana School of Medicine	(1932)		Louisiana
Johns Hopkins University School of Medicine	(1921)		Maryland
Ohio State University College of Medicine	(1923)		Ohio
Starling Medical College	(1892)		Ohio
University of Cincinnati College of Medicine	(1936)		Ohio
Western Reserve University School of Medicine	(1934)		Ohio
Meharry Medical College	(1941)		Tennessee
Baylor University College of Medicine (1930)	(1931)		Texas
University of Texas School of Medicine (1924)	(1930)		Texas
McGill University Faculty of Medicine	(1937)		Kentucky

School	LICENSED BY ENDORSEMENT	Year Grad
Tulane University of Louisiana School of Medicine	(1941)	

District of Columbia November Report

The District of Columbia Board of Examiners in Medicine and Osteopathy reports the written examination for medical licensure held at Washington, Nov 9-10, 1942 The examination covered 9 subjects and included 60 questions An average of 75 per cent was required to pass Eight candidates were examined, all of whom passed The following schools were represented

School	PASSED	Year Grad	Number Passed
George Washington University School of Medicine	(1935)		1
Georgetown University School of Medicine	(1940)		1
Johns Hopkins University School of Medicine	(1929)		1
Columbia University College of Physicians and Surgeons	(1938)		1
University of Pennsylvania School of Medicine	(1941)		1
Medical College of Virginia	(1941)		1
McGill University Faculty of Medicine	(1941)		1
Osteopath*			1

* Examined in surgery only

Vermont June Report

The Vermont State Board of Medical Examiners reports the written examination for medical licensure held at Burlington, June 16, 1942 The examination covered 12 subjects and included 90 questions An average of 75 per cent was required to pass Twenty candidates were examined 19 of whom passed and 1 failed The following schools were represented

School	PASSED	Year Grad	Number Passed
Syracuse University College of Medicine	(1942)*		1
University of Rochester School of Med and Dentistry	(1940)		1
University of Vermont College of Medicine (1942 16)*	(1941)*		17

School	FAILED	Year Grad	Number Failed
Johns Hopkins University School of Medicine	(1917)		1

Ten physicians were licensed to practice medicine by endorsement from February through October 1942 The following schools were represented

School	LICENSED BY ENDORSEMENT	Year Grad	Endorsement of
Yale University School of Medicine	(1910)		New York
State University of Iowa College of Medicine	(1929)		Iowa
Johns Hopkins University School of Medicine	(1930)		Connecticut
Harvard Medical School	(1904)		Mass
Tufts College Medical School (1930)	(1939)		Nat Board
Cornell University Medical College	(1923)		Nat Board
Woman's Medical College of Pennsylvania	(1941)		Penn
University of Vermont College of Medicine	(1941)		Nat Board
University of Edinburgh Faculty of Medicine	(1900)		N Carolina

* Licenses have not been issued

Miscellany

MEDICAL STANDARDS FOR PHYSICIANS IN THE SCHOOLS PROPOSED BY THE AMERICAN ACADEMY OF PEDIATRICS

In 1937 the Committee on School Health of the American Academy of Pediatrics proposed five principles to guide in the development of medical services for public schools Last year the committee reemphasized the second principle which was concerned with medical standards and the maintenance of quality of service We quoted from one of the principles of the American Medical Association The responsibility for the character of medical service must be borne by the medical profession and declared The advice which is given to parents pupils or school staff should meet the best medical standards

While the soundness of these principles has not been questioned a neglect of medical standards has been almost characteristic of school service until very recently and still too many places allow the responsibility for the character of medical service to be borne by lay administrators Organization plans generally provide no way of being sure that the school administrators decisions will be made with the benefit of a full understanding of medical problems

If the schools are to make a more effective use of their strategic position to educate parents and children to use curative and preventive medical services intelligently then the great professions of education and medicine must work together in a common cause Some plan of administration is necessary for educational matters to be guided by educators and for medical policies to be determined by physicians There must be a plan that avoids decisions made on administrative convenience only rather than on professional principles

ORGANIZATION PLANS

As the physician in the schools may receive his direction from the health department, the education department or a combination of the two departments we should consider how each type of organization may be planned to conform to our medical principles

1 The administrator of a school health service under a health department should provide for a medical administrator to give direction and leadership in interpreting medical standards With civil service or other plans for a merit system the qualifications of personnel must be decided according to a sound interpretation of needs Either through the board of health or through a special medical advisory committee the executive should have the support and advice of real medical leadership From the education department he should also have such an organization plan as will provide at all times for ready consultation and leadership of the educational staff

2 If the administration is under the education department there is often a problem of obtaining a medical executive for the smaller school systems unless a full time medical executive can be arranged to serve several school districts or for the medium sized school systems unless the executive can be combined with the medical staff part of the service on a full time basis In either case a medical advisory board is needed to safeguard professional qualifications and conditions of employment for the medical staff A board for determining essential broad policies is an accepted and well tried plan to safeguard the public welfare by providing advice, support and control of the executive

3 When the school health service is administered under joint control of the health and education departments the need for a medical executive can usually be supplied through the health department's contribution, or by a special medical administrator responsible to a joint board The joint board from both departments should direct or advise the medical staff Sound public service demands that the public always have the benefit of the recognized channels of organized medicine for determining medical standards If these standards are to be applied for the selection of medical personnel and for determining the conditions of employment for physicians, then an organization plan must provide the means for interpreting how the standards may best meet the needs of an individual situation

PROFESSIONAL QUALIFICATIONS

There is, therefore, need for two kinds of professional standards for medical personnel

- 1 For medical administrator
- 2 For staff physician

The medical administrator should meet in addition to basic pediatric training standards of training and experience in public health administration and education, and the staff physician should meet qualifications in clinical and preventive pediatrics

While full time medical personnel is recommended for administrative positions the requirement of full time for staff positions is likely to discriminate against the more competent, ambitious and well qualified clinicians because the more competent physicians are not likely to be willing to give up the rewards available to them through private practice. Until the pay for staff positions can be made very much more inviting the most competent physicians will be available for staff positions only on a part time basis

As far as qualified physicians are available preference should be given to those physicians who meet the following qualifications in the order named

- 1 Specialist certified by the American Board of Pediatrics
- 2 Fellow of the American Academy of Pediatrics or qualifications meeting academy requirements
- 3 Alumnus of hospital registered by the American Medical Association and with residency fellowship in pediatrics
- 4 Alumnus of hospital registered by the American Medical Association which included service of one year in pediatrics where there is an approved residency or fellowship in pediatrics (Communicable diseases included in pediatrics)
- 5 Alumnus of hospital registered by the American Medical Association (one and one half year internship and an appointment in pediatrics to a registered hospital, including outpatient department or hospital appointment)
- 6 Part time specialty in pediatrics with pediatric appointment in registered hospital

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts Indispensability of Record of Board as Evidence in Appeal Proceeding from Revocation Order—The petitioner's license as a drugless practitioner was revoked with the proviso that if he would sign a stipulation to refrain from the use of all advertising except the use of the words "drugless practitioner" on his professional card his license would be restored and he would be placed on five years probation. The petitioner sought a writ of mandamus to compel the respondent board of medical examiners to restore his license. The trial judge suggested that a transcript of the proceedings had before the board should be introduced in evidence by the petitioner, but the petitioner refused to produce the transcript on the ground that he was entitled to a trial de novo without reference to the evidence produced before the board. The trial judge held that the introduction of such transcript was a jurisdictional prerequisite, that in its absence no other evidence could be presented, and denied the petition for mandamus. From this ruling the petitioner appealed to the district court of appeal, first district division 1 California.

The petitioner contended that when a practitioner has had his license revoked by an administrative board exercising state-wide functions and seeks by mandamus to have such license restored he is entitled to a trial de novo in the literal sense and that the evidence introduced before the administrative board is incompetent for any purpose. The board contended on the other hand that on the trial of the mandate proceedings the record of the board's proceedings must be introduced as a condition precedent to the further exercise of jurisdiction and that the only additional evidence authorized is subsequently discovered evidence or evidence improperly excluded by the board.

In the opinion of the appellate court, neither contention was entirely sound. A petitioner in a mandamus proceeding of this kind is entitled to a trial de novo in which the trial court must exercise an independent judgment on the facts, the petitioner is not limited to the record made before the board but may introduce additional evidence. But the board's record is legal, competent evidence so as to be admissible over the objections of one of the litigants. Such record, however, is not indispensable evidence so as to justify the trial court in refusing to proceed unless the petitioner produces it. If the record is produced by either it must be admitted but if neither produces it a trial court has no power to compel its production or to refuse to proceed unless introduced.

The petitioner next contended that even though no evidence was introduced, the allegations of the petition for mandate and the answer and return thereto demonstrate, as a matter of law, that no offense warranting discipline was committed by him. The complaint filed before the board charged that the petitioner (1) used the prefix "Dr" in a window sign in connection with his name without otherwise indicating the type of certificate possessed by him and that the petitioner did not hold a physician's and surgeon's certificate, and (2) that he used the letters "N D" as a suffix to his name in a window sign, which indicated that he was entitled to practice naturopathy but that at the time he was not licensed to practice naturopathy. A section of the Business and Professions Code provides: "Unless a person licensed and authorized under this chapter or any preceding medical practice act to use the title 'doctor' or the letters or prefix 'Dr' hold a physician's and surgeon's certificate the use of this title or these letters or prefix without further indicating the type of certificate he holds, constitutes unprofessional conduct within the meaning of this chapter." The constitutionality of statutes requiring all practitioners except physicians and surgeons to indicate the type of certificate held in connection with the use of the title "Doctor" or "Dr" is not open to question, said the court. There is a reasonable ground for such distinction. In common parlance the term 'doctor' is customarily used to refer to physicians and surgeons. The legislature was justified in believing that the use of such title by others without descriptive designation would tend to indicate to the public that the user is a physician or surgeon. The court therefore ruled against the petitioner's contention that this provision in the California law was unconstitutional class legislation.

With respect to the charge that the petitioner used the letters "N D" as a suffix to his name in a window sign it was admitted that his license as a drugless practitioner authorized him to treat diseases, injuries, deformities or other physical or mental conditions without the use of drugs or what are known as medical preparations and without in any manner severing or penetrating any of the tissues of human beings except the severing of the umbilical cord. It was clear to the court that naturopathy is a form of drugless practice within the statutory definition quoted. If the petitioner possessed the degree of doctor of naturopathy, as he alleged there was no violation of the Business and Professions Code in the use of the letters "N D." Whether or not he possessed the degree, however, was a question of fact to be determined by the trial court.

Because the trial court erroneously refused to proceed unless the board's record was produced by the petitioner and because of the existence of certain factual situations which required a determination by the trial court the judgment in favor of the board was reversed.—*Darc v. Board of Medical Examiners of State of California* 127 P (2d) 977 (Calif 1942)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Analysis of Gastroscopies.—Analysis of 938 consecutive unselected gastroscopies of 842 patients by Renshaw and his associates demonstrated that in 217 the method was of major value in establishing the diagnosis when all other examinations were negative or indeterminate. Gastroscopy was of minor additional value in 566 cases in that it did not alter the major diagnosis, treatment and prognosis. For the most part the minor contribution was confirmatory for roentgen study. In the remaining cases its major limitation was that in some the roentgenologist reported either a definite or suspected lesion but the area in question could not be seen by the gastroscopist. In a few not only could the area in question not be seen but also other large areas or the major part of the stomach could not be satisfactorily visualized. In others the examination could not be completed because of spasm of the esophagus, acute angulation of the esophagus or angulation of the instrument beyond its useful range. The amount of distress suffered by the patient was but a minor limitation compared to the amount of distress of the average patient after an Ewald test meal. For comparing these two dissimilar complementary or supplementary but not competitive methods 170 cases were selected that had been followed long enough to establish the diagnosis at operation or at necropsy. Only the first gastroscopy and roentgenoscopy made at comparable times were considered. Both methods agreed in 109 of the 170 cases, both were wrong in 9 and both were indeterminate in 14. Roentgenoscopy was correct and gastroscopy indeterminate in 15 while gastroscopy was correct

and roentgenoscopy indeterminate in 23. The fact that one method may be indeterminate while the other may establish the diagnosis further emphasizes the fact that the methods are complementary and that often both methods are required for a complete and comprehensive diagnostic investigation.

Rheumatic Recrudescences.—Of the 64 children given sulfanilamide (or sulfathiazole or sulfadiazine in a few cases) for four seasons from October into June for the prevention of a recurrence of rheumatic fever only 2 received the drug for all four seasons, 5 for three seasons, 9 for two seasons and 37 for one season. Hansen, Platon and Dwan found the age, sex, socioeconomic status, number of attacks of rheumatic fever and degree of cardiac involvement comparable in 32 control subjects. All the children studied were between 3 and 16 years of age. Only 2 of the 53 treated with sulfanilamide experienced a rheumatic flare up and in 1 this occurred within six days of starting chemotherapy. On the other hand 17 of the 32 control children had a total of twenty one rheumatic recrudescences. In 5 these recurrences were moderately severe in 7 mild and in 6 they were choreic. In addition the trend in degree of cardiac involvement, size of the heart and functional classification were more favorable in the treated children. There appeared to be no difference in the number of infections of the upper respiratory tract in the two groups. The treated patients gained as well as the control patients and from a clinical point of view tended to be in better condition. Improvement, though suggestive in the electrocardiographic tracings of several patients could not be attributed to the effects of the drug alone. Although the series is small, the results of chemotherapy were consistent and when interpreted in the light of the results of other investigators they appear to justify further similar study, especially when the disease is one of the major causes of disability and death in children of school age in the temperate zone. Every child so treated should be under the constant care of a physician.

Pneumothorax Treatment—Between 1921 and 1939, 770 patients were selected for pneumothorax treatment. The treatment of 157 was rated as unsuccessful and discontinued in less than three months, 243 were not adequately traced, as they left the sanatorium for various reasons and had their pneumothorax carried on elsewhere. Treatment of the remaining 370 was carried on at the sanatorium and after discharge at the ex-patient clinic for an average of five and a half years after pneumothorax was discontinued. Of these 370 patients Morris states, 245 are able to work full time, 23 part time, 27 are still being treated and 75 have died since collapse was instituted. The ineffectiveness of collapse, a moderate contralateral lesion at the onset, a massive effusion and empyema, a severe contralateral spread of the lesion during collapse and the necessity of discontinuing pneumothorax in less than two years influenced the end result unfavorably. At the time of reexpansion the cavity of 96.3 per cent was closed and the sputum of 89.6 per cent was negative. The anatomic end results in the reexpanded lung, were excellent in 235 very good in 162, fair in 32, poor in 253 and non-expandable in 29 per cent. Relapse in either the collapsed or the contralateral lung occurred in 35, of these patients less than one third died. The most unfavorable complication of pneumothorax was the development of a large effusion this occurred in 29 per cent of the patients and appreciably increased the chances of an unfavorable outcome. In one fourth of these patients with large effusions empyema developed, and almost one half of the latter patients died. The total mortality from empyema was 35 per cent and the incidence 71 per cent. Pneumothorax in spite of its hazards is still a valuable method of treating properly selected patients, especially those whose disease is rapidly progressing in spite of bed rest.

Ambulatory Pneumothorax—Tice discusses results of pneumothorax in 4,810 of 6,481 tuberculous patients (treated during the ten years preceding July 1941) who had ambulatory care, in 2,586 it was combined with sanatorium care. The disease of only 5 per cent was in the minimal stage and of the rest it was moderately or far advanced, the sputum of 73 per cent was positive when treatment was started, and cavitation was present in 60 per cent. At the time of the report 60 per cent were living, 25 per cent were dead and 15 per cent could not be traced. Excluding the patients who died, 21 per cent gained 5 to 10 pounds (2.3 to 4.5 Kg.), 20 per cent 10 to 20 pounds (4.5 to 9 Kg.) and 15 per cent gained 20 or more pounds. The weight of 32 per cent remained stationary and that of 12 per cent decreased. Excluding nonemployables, such as housewives, students and children, 41 per cent of the patients given ambulatory pneumothorax were employed at the time of the report. Another 13 per cent were physically employable but apparently, unable or unwilling to find work. It may be

well to consider the possibility of ambulant pneumothorax as a rehabilitative measure. Of the 2,224 treated exclusively in the clinics, 53 per cent were living at the time of the report as against 56 per cent of those receiving sanatorium treatment exclusively. Of the patients receiving both institution and clinic treatment 73 per cent were living at the time of the report. The disease of 31 per cent of the 2,800 patients with reexpanded lungs is classified as arrested, of 20 per cent as apparently arrested, of 7 per cent as quiescent, of 21 per cent as improved and of 21 per cent as unimproved. Of the 2,000 patients still under collapse treatment, 90 per cent are classed as improved and 10 per cent as unimproved. The influence of the initial diagnosis on the end results is shown by the following figures. Of 5,500 known cases, 96 per cent with minimal disease were living, as against 81 per cent of those with moderately and 63 per cent of those with far advanced disease. These results clearly indicate the value of collapse therapy in early tuberculosis. Considering pneumothorax with or without ancillary measures, thoracoplasty combined with other procedures gave the best results, 74 per cent living against 60 per cent living for pneumothorax alone, 56 per cent for pneumothorax and the phrenic operation combined and 45 per cent for phrenectomy alone. The results balanced against the time elapsing since treatment were considered satisfactory.

Extrapleural Pneumothorax—During 1938 and 1939, 75 patients were subjected to extrapleural pneumothorax. Geary's report deals with the results after an average postoperative period of slightly more than forty months. The early results were reasonably good, but as the postoperative period increased so did the complications. The most serious was infection of the established extrapleural pneumothorax space which often developed late. It was present in 37.3 per cent of the patients. The operation is as dangerous as thoracoplasty, while the obliteration of an unsatisfactory extrapleural pneumothorax space by thoracoplasty is more dangerous at times than a thoracoplasty as a first operation. The space was abandoned in 2 cases because the pneumothorax was no longer thought necessary. There is little tendency toward reexpansion of a lung that has been collapsed by prolonged extrapleural pneumothorax. Routine conversion of the pneumothorax spaces into olothorax has not been adopted. Because of the operative risk the frequency of complication and uncertain end results, extrapleural pneumothorax is unsatisfactory.

Sulfadiazine—Finland and his associates used sulfadiazine at the Boston City Hospital in 460 cases of streptococic, staphylococic and gonococic infections, the bacterial meningitides and infections of the urinary tract. Usually sulfadiazine was used only if other sulfonamides had not already been given, and treatment was continued when toxic effects resulted from other sulfonamides and further chemotherapy was necessary. Sulfadiazine may be accepted as the drug of choice in hemolytic streptococcus infection and in the various acute bacterial meningitides. In acute gonococic and staphylococic infections and in the acute infections of the urinary tract the efficacy of sulfadiazine in most cases is probably similar to that of sulfathiazole,

but because of its lower toxicity sulfadiazine is probably the drug of choice, particularly when therapy is to be prolonged. The authors' results and those of others seem to justify the claim that sulfadiazine is the drug of choice for initiating chemotherapy in acute pulmonary infections and for continuing treatment when the causative organism is the pneumococcus, the streptococcus and probably also the staphylococcus and Friedlander's bacillus. Toxic effects attributable to sulfadiazine are relatively few and mild. The comparatively frequent complications of the urinary tract warrant the control of its dose in relation to fluid intake and output, particularly for old persons, patients with hypertension and every patient with a probable impairment of renal function. The occurrence of agranulocytosis in 1 patient after prolonged therapy suggests that, despite the infrequency of this complication, it must be looked for in all patients treated with sulfadiazine for two weeks or more. Early recognition and prompt withdrawal of the drug will probably avert death. 'Sensitization' was not observed in any of the 21 patients who received a second or third course of sulfadiazine. However, its possibility has not been excluded. Epileptics were reactivated on early readministration of sulfadiazine to 1 patient. Other rashes and febrile reactions, known to occur when the drug is given after a brief interval, have not appeared.

Clinical Significance and Treatment of Pyuria.—The following data are given by Braasch in his summary of the clinical significance and treatment of pyuria. Pus cells in the voided urine of a female patient have little or no clinical significance. In such instances a catheter specimen of urine is necessary. Pus cells in the voided urine of the male patient are of greater clinical value, particularly if they are in evidence after the two glass test. It is of equal importance to determine the type of bacteria present in the urine. Intelligent treatment of pyuria is dependent on a knowledge of its bacteriologic aspects. Bacillary infection from colon bacilli or *Aerobacter aerogenes* is usually found. If mixed infection is present it is most often caused by colon bacilli with *Streptococcus fecalis*. Unless this fact is recognized, chemotherapy may fail. Renal tuberculosis which resists chemotherapy is a frequent cause of pyuria. Recently the symptoms and severity of this infection have become milder and its recognition often is difficult. Pyuria may be coincident with lesions in other organs, such as acute cholecystitis. Urinary infection as a rule does not interfere with operation, but a search should be made for the cause of the pyuria. A careful search for foci of infection and their removal are always necessary. Pyuria or a history of previous urinary infection occurring with hypertension demands a complete urologic investigation. In the presence of pyuria important clinical data can be obtained by such simple tests as the making of roentgenograms and excretory urograms. Intelligent chemotherapy depends on identification of bacteria. Persistent pyuria, in spite of indicated chemotherapy, usually is caused by some underlying pathologic lesion in the urinary tract which requires careful treatment.

Thrombophlebitis, Phlebothrombosis and Pulmonary Embolism.—As deep phlebothrombosis of the femoral or calf venous plexuses is a source of pulmonary embolism, Evans suggests that, if the patient is more than 50, section of the femoral vein should be seriously considered. If such patients have already suffered a warning embolism, ligation and section of the femoral vein or of the external iliac vein is indicated. Phlebothrombosis in the pelvic veins is a dangerous source of pulmonary embolism. Prolonging the clotting time by heparin or dicumarol or both prevents propagation of a clot in the pulmonary artery should embolism occur. In phlegmasia alba dolens, early lumbar sympathetic procaine block is best, although surprisingly good results have been obtained in chronic cases. There is relatively little danger of pulmonary embolism in typical "milk leg." Thrombophlebitis migrans, thrombophlebitis of the upper extremities and the thrombophlebitis of Buerger's disease rarely cause pulmonary embolism. However, propagation of the clot into the deep veins of the leg must be watched for in phlebitis migrans. Isolation of an involved segment of vein by ligation may be necessary. Compression bandages, rest (off the feet but not in bed) and sulfathiazole are of value. Heparin or dicumarol may be needed to stay the progress of the clot in thrombophlebitis in the upper extremities.

Intracutaneous Inoculation of Poliomyelitis Virus.—Trask and Paul collected stools from 9 monkeys and 1 chimpanzee previously inoculated intracutaneously with poliomyelitis virus. The animals were placed in cages according to the four or five species and were observed for signs of experimental poliomyelitis. Stools were collected daily from each cage and weekly pools were tested for the virus. Fourteen of the post-inoculation tests were negative and three were positive. The virus was detected in the first postinoculation week in the pooled stools of 2 green monkeys and in the chimpanzee's stools collected during the first and second postinoculation weeks. The most severe poliomyelitic infection occurred among the cynomolgus and mormon monkeys. Green monkeys had typical mild paralytic poliomyelitis. The mildest infection appeared in the chimpanzee. The authors believe that their detection of the virus of poliomyelitis in feces is the first study of its kind to be reported.

Renal Function and Hypertension.—Dalton and Nuzum demonstrate that in spite of apparently small differences from normal a significant reduction exists in the ability of the kidneys of patients with essential hypertension to concentrate urine and to excrete phenolsulfonphthalein. This reduction is demonstrated only when the data on hypertensive and on normal persons are considered collectively for the respective groups instead of as individual comparisons. The age of the normal or hypertensive person or the duration of the disease has no effect on the renal function. An increase in the severity of the disease indicated by a rise in diastolic pressure is accompanied by a reduction of renal function. Alkaline diets apparently delay the excretion of fluids.

Vasodepressor Carotid Sinus Reflex.—Sigler studied the vasodepressor effect of the carotid sinus reflex of 700 ambulatory patients and he determined the frequency and the severity of this reflex in the two sexes at various ages and at various levels of blood pressure. Most of them presented evidence of cardiovascular disease, but many were free from such disease. The patients were divided into four groups: those with a blood pressure of less than 150 systolic and 90 diastolic and those with a systolic pressure from 151 to 175, 176 to 200 and more than 200 with a respective diastolic pressure from 91 to 105, 105 to 125 and more than 125. Roughly, 88 per cent of the 447 male patients and 82 per cent of the 253 female patients showed a drop in pressure. If a drop of less than 10 mm is considered of insufficient significance the response is reduced to about 78 per cent for the male and 71 per cent for the female patients. The response occurred more frequently and was more pronounced in older persons. Also the higher the blood pressure the more frequent and decided was the response. A drop was more frequent in the systolic than in the diastolic pressure. A drop in pressure often occurred in patients without cardiomegaly but was more frequent in those who also showed cardiomegaly. The frequency and the degree of vasodepression were roughly the same in those with and those without cardiomegaly. In many there was a definite difference in the response to stimulation on the two sides. The amount of stimulation required to produce the maximal response varied from person to person and with the position of the patient. The data point to an inherent instability in the vasomotor system in persons who

show a decided vasodepression induced by the carotid sinus reflex. The seat of this instability is either in the medullary synapses or in the vasomotor terminals of the vascular tree. Arteriosclerosis is possibly one of its underlying predisposing causes, especially as the reflex is most prevalent under circumstances in which arteriosclerosis is apt to occur—that is, in a man of advanced age with pronounced hypertension.

Hyperthyroidism—To determine whether or not subtotal destruction of the thyroid could be achieved with roentgen therapy and what dosage would be required, Soley and Stone irradiated the thyroid area of 43 hyperthyroid patients. Routinely the patients received 150 roentgens to each lobe of the thyroid every day for six days, thus 900 roentgens was administered to each lobe. During the same period the patients received 150 roentgens every second day to the thymus region. The study was begun in 1935 and ended in September, 1940. Of the 43 patients 31 had toxic diffuse goiter and 12 toxic nodular goiter; of the latter, 7 had had an operation, 2 had what might be called nodular involution and 3 had toxic nodular goiter not previously treated. Thirty patients of the series had not been treated surgically and 13 had recurrences after operation. The average fall in the basal metabolic rate was 35.7 per cent for the 37 patients who were either 'cured' or improved. Twenty-five patients may be called 'cured' that is they were free from signs or symptoms of hyperthyroidism (with the exception of residual exophthalmos), 8 were definitely improved and would probably have been called 'cured' by many workers, 3 were inadequately followed and 1 was treated in preparation for operation. If this last patient the 2 who were treated in the hope of relieving their hyperthyroidism before they died of congestive heart failure and the 3 who were inadequately followed are eliminated the results show that of the remaining 37 patients 25 were cured, 8 were decidedly improved and 4 not improved. Twenty-two of the patients received iodine and 21 did not in conjunction with the roentgen therapy. The cure or improvement occurred in an average time of eight and seven tenths months from the onset of treatment. Complications consisted of tracheitis and esophagitis in 15 patients. To avoid these complications radiation is now given through one port anteriorly.

Tracheotomy in Laryngo-tracheobronchitis—During the period from 1931 to 1940 1360 cases of nondiphtheritic infectious obstruction of the larynx, trachea and bronchi were observed in the Willard Parker Hospital. Intubation in addition to aspiration, was required to relieve the obstruction in 121 and tracheotomy in 126, while 1,113 were treated by nonsurgical measures. Neffson points out that during the first seven years the incidence of tracheotomy increased from 53 per cent to 19.4 per cent in the last three years. During this time the incidence of intubation scarcely varied—87 to 9.4 per cent—but the mortality rate dropped from 43 to 28 per cent respectively during the seven and three years. From the various arguments of otolaryngologists, pediatricians, statisticians and discussions, Neffson believes that if specially trained residents are

available intubation in properly selected cases is the method of choice. If the patient is given an opportunity to fight the acute infection before he is compelled to cope with the added burden of an operative procedure and an alien respiratory physiology, his chances of recovery are increased. When ideal conditions for intubation do not exist, tracheotomy is to be preferred. A high incidence of *Staphylococcus aureus* infection has been observed during the last three years. It is probable that this organism is a secondary invader in a primary virus infection. The use of sulfathiazole or sulfadiazine is recommended if chemotherapy is resorted to before the infecting organism has been identified. Intubation is not the single important factor in prolonged crumulation. It is due also to the dense infiltration of the subglottic tissues, the formation of occasional strictures and webs which do not necessarily result from the intubation, the occurrence of prevertebral edema with compression of the trachea and tracheal stenosis around the wound. Of 153 patients who survived intubation, tracheotomy or both 51 were seen from one to ten years later and the 21 who had been intubated showed no vocal alterations as to quality, pitch and intensity. Likewise there was no change in the voice of the 4 children who had had a tracheotomy. One of the 26 persons who had had intubation and tracheotomy was moderately hoarse and 1 extremely hoarse, the rest showed no changes. Eleven of the 51 patients had had repeated attacks of mild croup.

Superficial Vascularization of Cornea—Sundstead discusses the prevalence of superficial vascularization of the cornea in groups of school children, youths and adults of various sizes and the effect that riboflavin therapy had on the condition. The 366 persons examined were residents of Hagerstown, Md. or its immediate vicinity. Fifty-two of those examined were given riboflavin. From 80 to 95 per cent of a group had some degree of corneal invasion by epithelium. Corneal invasion was relatively more frequent and more severe among the older groups of persons. Of the parochial school children 67 per cent had no more than two quadrants of the National Youth Administration youths 17 per cent had only two quadrants affected and among the older group the figure was 30 per cent. The corneal vascularization of 15 older subjects who had received 615 to 1630 mg. of riboflavin during at least sixty days was not significantly different from that of 15 control persons of similar age. Likewise the therapeutic effect was similar in the 11 parochial school children given 5 mg. of riboflavin daily for forty-nine days and the 11 controls. It appears doubtful that superficial corneal vascularization is a diagnostic sign of riboflavin deficiency.

Health of the Doctor—Gosse discusses the amount of ill health and its various causes among 8,884 medical men from 25 to 65 years of age. The year 1938 was chosen for a detailed analysis, as it was the last prewar year and there was no epidemic. The ill health of the doctor is divided into those diseases which cause death and those which disable him from following any part of his professional work for at least seven days. The mortality of the doctors increased in each decade. As each man is exposed to the annual death rate for his decade for ten years before he passes into the next decade, his risk for each decade must be ten times the annual risk. In other words 3 out of 4 doctors live to be 65. There were forty-one deaths among the 8,884 men. To determine the causes of early death among doctors the author, in addition to the year 1938, also took the year 1939 and up to May 1940 so as to get a hundred consecutive deaths among the 8,884 doctors. The causes were cardiovascular degeneration in 17, malignant growths in 15, pneumonia (pleurisy) in 12, coronary thrombosis in 10, hemiplegia in 9, suicide misadventure and accident in 12, pulmonary tuberculosis in 4, disease of the right side of the heart in 3, congenital aneurysm in 2, various infections in 11 and the rest 1 each from aortic aneurysm and prostatic blood and ulcerative (duodenal) disorders. During 1938 1,620 of the 8,884 doctors were ill for more than a week, a total of 10,982 weeks. Of the 1,620, registered medical practitioners certified 351 as suffering from respiratory infections, 276 from influenza, 100 from accidents and less than 100 each from inflammation of connective tissue, anxiety state, fibrositis, appendicitis and infections of the hand, less than 50 each from disorders of the special senses, peptic ulcer, disorders of the central nervous system, degenerative cardiovascular disease, pyelitis, cystitis and pneumonia, less than 20 each from pulmonary tuberculosis, renal disease, gallbladder, jaundice, mumps, asthma, coronary thrombosis, rheumatic and osteoarthritis, acute rheumatism, insanity, colitis, malignant growths and pleurisy, less than 10 each from auricular fibrillation, measles, scarlet fever, diphtheria, prostaticitis, chickenpox, ischio-rectal abscess, angina pectoris, glandular fever, erysipelas, gout, whooping cough, diabetes, hyperthyroidism, valvular heart disease, undulant fever, thyroid disease and typhoid, and 156 from unclassified causes. As a check on these figures the amount of sickness among 100 consecutive doctors who had reached the age of 65 was investigated. They had been under observation for an average of thirty and three-fourths years and had suffered 3,314 weeks of illness—that is, an average of seven and five tenths days every year from the age of 35 to 65. Seven of these 100 doctors did not have a week's continuous illness during their working lives. That coronary thrombosis is the doctor's disease is challenged by the author. He found that the parental history as to cardiovascular degeneration was the same for 37 doctors in whom coronary thrombosis developed as for a control group of 37 who were still working at the age of 65, both of which groups were passed as fit at 30. The parental history for pulmonary tuberculosis was the same for 37 doctors in whom pulmonary tuberculosis developed as for a control group of 37 still working at the age of 65, both of which groups also were passed as fit at 30.

Clinical Significance of Rh Factor—In every case of erythroblastosis that Boorman and his associates examined the serum of the mother contained an immune agglutinin which was incompatible with the infant's erythrocytes. In 44 of 48 cases the agglutinin was anti Rh. In the remaining 4 it was either anti A or B. Because of this latter observation it is considered that the anti A and B agglutinins are capable of destroying the erythrocytes in a certain number of infants and thus of being the main causative factor of the erythroblastosis in some instances. The finding of weak Rh antibodies in the serum of the mothers of some babies with physiologic jaundice supports the idea that there is no clearcut distinction from the clinical point of view between mild and severe jaundice of the newborn. At present if serologic tests are used to aid the diagnosis of doubtful cases of erythroblastosis, compatibility of the mother's serum with the infant's erythrocytes may be regarded as a strong point against the diagnosis, provided the mother's serum is examined by a sensitive technique seven to twenty-one days after delivery. On the other hand if the mother's erythrocytes are Rh negative and her serum contains anti Rh agglutinin the diagnosis is strongly supported. A change in the method of selecting blood donors is urgently needed particularly in the transfusing of recently delivered women and whenever there is any suggestion that the infant is affected with erythroblastosis or when there is a history of the previous birth of jaundiced or unexplained stillborn babies. At the same time the present method of testing for compatibility between the bloods of donor and recipient must be modified. Every blood bank should establish a panel of group O Rh negative donors.

Sulfonamide Sensitization—Erskine recommends that whenever possible small doses of the sulfonamides be used in some chronic infections so as to desensitize the patient especially as the drugs are used for so many common illnesses and the fact that a patient in whom a sensitivity of this type develops may remain allergic for a long time. Sometimes the first tablet given months later may provoke an immediate return of a dermatitis with general symptoms and these reactions may occasionally be of an alarming nature. Delayed reactions have not been observed when desensitization was undertaken at the time of the reaction. If chemotherapy is restricted whenever possible, to seven days or less the incidence of allergic sensitivity is considerably reduced. Sensitivity almost invariably appears between the eighth and tenth days of treatment and depends more on the factor of time than on the total dose employed. Occasionally delayed reactions appear up to forty-eight hours after chemotherapy has been stopped so that administration for more than six days makes sensitivity a possibility. Absorption from local applications as well as oral or parenteral administration may lead to sensitization phenomena. Desensitization should be undertaken immediately if eighth day allergic sensitization is encountered. The drug should be withheld if Werner's test indicates drug retention. In photosensitization the drug may be safely continued if further exposure to sunlight is avoided.

Hemimechanics and Sedimentation Rate R. B. Whittington and A. K. Miller—p. 195

*Clinical Trial of Tubercle Endotoxin in Pulmonary Tuberculosis W. G. Bridges—p. 203

'Tubercle Endotoxin' in Pulmonary Tuberculosis—Bridges compared the effect of endotoxin in 100 cases of pleuropulmonary tuberculosis with an equal number of cases under identical conditions and given the same treatment but no endotoxin. The drug used was tubercle endotoxin, prepared

according to Grasset's formula by a British manufacturing chemical firm "a preparation of the tubercle bacillus from which the toxicity has been eliminated." During the first week two doses of 0.05 cc at an interval of three days were given subcutaneously. Thereafter two weekly doses were given, every week the dose was increased by 0.1 cc until two doses of 0.5 cc were given in one week, then one dose of 1 cc fortnightly for a further two months, making a total period of six months of treatment. From the data obtained, tubercle endotoxin had no influence on the course of tuberculosis of the adult type in this country. There was, seemingly, a possible but unproved comparative benefit to patients treated by artificial pneumothorax and to those with bilateral disease but this possibility carries no weight, owing to an insufficient number of patients and other factors.

 Asthma and Histamine Therapy. A. Dudman — p. 821

Eosinophilic Pulmonary Infiltration—According to von Meyenburg transient pulmonary infiltration with eosinophils, first described by Löffler in 1932, is a benign disorder. The author reviews postmortem observations on 4 patients 3 of whom died as the result of military accidents and a fourth of a traumatic tetanus of short duration. The first man died following a gunshot wound which had caused hemorrhage from a torn renal artery. The right lung contained two dense, airless foci the size of a plum and a cherry respectively. These were believed to be ordinary bronchopneumonic foci. Since the man had been healthy, it was supposed that he had had a mild influenza and that the dense pulmonary foci represented a residue of nonabsorbed inflammatory virus. It was disclosed that four weeks before the man had had a mild influenza without pulmonary symptoms. Microscopic study of the pulmonary tissue revealed a large number of eosinophils while examination of other organs revealed eosinophilia of blood and bone marrow. In 2 of the other 3 cases ascariids were discovered in the intestine. Two of the 4 patients had bronchitis and bronchiolitis these 2 patients had bronchopneumonia, the others had lobar pneumonia. The author believes that these cases present an anatomic substrate of a transient pulmonary infiltration with eosinophils, though he is not able to furnish proof of its transient nature. The pathogenesis or rather the route of development is not always the same. Evidence is presented that there is not only a bronchogenic but also a hematogenic development and that eosinophilic infiltrates occur not only in the lungs but also in other organs. There is evidence of a possible relationship between epididymitis and pulmonary infiltration. His studies furnish no evidence of bacteriologic nature. Possible etiologic significance of animal parasites is admitted. The author concludes that eosinophilic pulmonary infiltration is an inflammatory allergic reaction to various antigens which may enter the body by various routes.

Sugar Absorption and Phosphate Metabolism in Rickets—Laszt and Dalla Torre state that, although rickets has long been recognized as a vitamin deficiency disease, knowledge of the rachitic metabolic processes and of the effect of vitamin D on it is still inadequate. As the chief disorders in rickets they mention disturbances in the ossification in the intestinal absorption and in the intermediate metabolism. They cite observations which indicate that in rickets a change in the composition of serum is more important than disturbances of the bony system. The inorganic phosphate content is greatly reduced in rachitic serum, and it is assumed that the phosphate cannot be absorbed from the gastrointestinal tract. The authors had observed earlier that carbohydrates during absorption from the small intestine exert a specific stimulus on the phosphate secretion. This secreted phosphate causes the selective absorption of monosaccharides. If the retroabsorption of the secreted

phosphate is inhibited, the selective sugar absorption ceases. Thus, if the phosphate absorption is disturbed, this would have to be evident in the sugar absorption. The authors investigated this on rats. 1 They were able to prove that in rachitic rats the absorption of phosphates from the small intestine is inhibited. 2 There exists an inhibition of reabsorption of the phosphate secreted in the intestine during the sugar absorption. 3 The slow reabsorption of the secreted phosphate causes an inhibition of the sugar absorption. 4 Calcium chloride and calcium lactate absorption exert no stimulus on the secretion of phosphate. 5 The conclusion is reached that vitamin D acts as a transformer of phosphate in that it transforms free phosphate to sugar. The rachitic metabolic disturbances are ascribed to the deficiency of this transformation in the organism.

Treatment of Whooping Cough by High Altitude Flights—Lauener and Maeder review observations on 244 infants and children and on 12 adults who were subjected to high altitude flights in the course of the convulsive stage of whooping cough. The duration of the flights was usually ninety minutes and about half of this period (forty minutes) was spent at altitudes of from 3,500 to 4,000 meters. The majority of the flights took place in the forenoon. The weather conditions were not always favorable for the flights. Rapid sliding flights from high altitudes were avoided because they produced pain in the organ of hearing. The children showed practically no fear or anxiety in the plane. The majority of infants and young children began to sleep at altitudes over 2,000 to 2,500 meters and awakened only on landing. The authors think that this is due to oxygen deficiency together with the monotonous noise of the motors. Nausea or vomiting appeared in about 30 per cent of the children and adults but no vomiting was seen in infants. A critical evaluation of the 250 cases on which data are available reveals that in 69 (27.6 per cent) the high altitude flight produced no effect whatever. In 5 children there was exacerbation. In the other 181 noticeable and striking effects were observed. In 57 (22.5 per cent) the flight was effective either immediately or within two or three days in 80 more (32 per cent) the cure was not so rapid nevertheless a considerable improvement was observed within a comparatively short time. In about 55 per cent the effects were quite favorable. In the remaining 44 (17.6 per cent) the effect was not striking, although not entirely negative. Twenty-four were taken by automobile to an altitude of 3,450 meters and remained there for three hours. 16 of the 24 showed a slight to noticeable improvement after this trip but in some the improvement was only temporary. The authors review observations on 65 patients who were treated in the low pressure chamber with an average stay of sixty minutes. Rapid cure was obtained in 31 per cent improvement in 50 per cent no betterment in 16 per cent and exacerbation in 3 per cent. The authors conclude that high altitude flights as well as the low pressure chamber exert a favorable effect on whooping cough. The low pressure chamber has the advantage that it is independent of weather conditions.

Pediatrica Pratica, São Paulo

13 1-98 (January-February) 1942 Partial Index

- First Week of Life of Premature Infants. R. Kohnan — p. 5
 Necessity of Treatment of Caries of Temporary Teeth. A. Campos de Oliveira — p. 21

First Week of Life of Premature Infants—Kohnan Y observed 4,680 infants who were born at a maternity hospital during the years 1938, 1939 and 1940. There were 585 premature infants (12.5 per cent), 48 per cent were born of unmarried mothers. Syphilis played an important role in the pathogenesis of prematurity, which was more frequent in multiparas than in primiparas. Proper care and administration of testosterone propionate improved the vitality of the premature infants. The rate of mortality in this group was 18.6 per cent. Obstetric manipulations increase the rate of mortality. Congenital syphilis, intracranial hemorrhage and congenital weakness are the main causes. These may be favorably influenced by intensification of the crusade against syphilis, protection of unmarried pregnant women by placing them in better social and economic conditions and by an increase in the number of medical and social centers for free medical care.

Book Notices

Urological Diseases of Pregnancy By E Granville Crabtree M.D. Urologist to the Boston Lying in Hospital Boston With a signed chapter by George C Prather M.D. Assistant Urologist to the Boston Lying in Hospital Cloth Price \$6.50 Pp 472 with 159 illustrations Boston Little Brown & Company 1942

This exceptionally complete treatise on the urologic diseases of pregnancy shows a wide experience in the urinary complications in gravid women and an extraordinary familiarity with the work of others in the field. There is a scope which is unusual in a volume devoted to a subject which superficially does not seem to have as many facets as the author most effectively discovers and describes. Most urologists at large hospitals which have active maternity services have come face to face with most of the problems which this volume recites but few have taken the profound interest in them or have acquainted themselves with the many changes affecting the gravid and parturient woman in relation to the urinary tract and other systems of the body. The large bibliography represents only those contributions which have been carefully analyzed and those of some value in clarifying the entire subject.

The importance of hormonal influence in pregnancy is stressed and the statement that "when this glandular response is abnormal, pathological changes are inevitable" is noteworthy. There are a few illustrative quotations which may be cited. "The response of the human body to pregnancy influences seems to follow a fairly constant pattern certainly so far as the urinary tract is concerned. While the composite curve is true to the form mentioned there are individuals in whom there is apparently no change whatever in the urinary channels during pregnancy. No explanation has been offered as to why one individual seems to respond to pregnancy more than another."

Chapter 6 is devoted to the effect of pregnancy on anomalous and preexisting pathologic conditions of the urinary tract. Here is considered solitary kidney, abnormal mobility of the kidney and malposed kidney. The subject is thoroughly covered. In chapter 9, besides other interesting data, the experimental work showing the effect of pregnancy hormones on the isolated ureter is abstracted. Chapter 12 contains a thorough exposition of infections of the urinary tract and comprises fifty-three pages. Chapter 14 is devoted to the treatment of urinary tract infections, and a mature evaluation of the various drugs in vogue is given. Again a few quotations may be cited. "In the low acidification therapy the diet which is tolerated by most pregnant women is not adequate for the cure of the infection. There is little to commend the ketogenic diet in comparison with other available antiseptics. Quoting Krueger and Scribner (1941), 'Theoretically, uncomplicated infections of the urinary tract should offer potentialities for the application of the phage therapy. They are usually well localized processes and the tissues involved are readily accessible, so that almost any desired amount of phage can be brought in contact with them. Nevertheless, there is little in the published results to suggest that phage therapy has any significant superiority over the common chemotherapeutic approaches.'"

Other subjects are equally well described in subsequent chapters. In chapter 21 the subject of fluid balance in pregnancy and the puerperium should be of great interest to the urologist from a mechanical point of view in relation to residual urine and retention after delivery because "he should not treat a patient to her disadvantage through lack of knowledge of the fundamentals of fluid behavior in relation to gestation. It has been shown that the percentage of output of water in normal pregnancy indicates a progressively decreasing ability to handle fluids with a moderate rise near term."

Chapter 34 deals essentially with renal insufficiency from blood transfusion. This subject also is of great importance because often the need for blood replacement in postdelivery cases is urgent and the amount of blood required may be a large percentage of the blood volume of the patient at the time of transfusion.

In general this volume which is attractively printed and illustrated, may be considered a milestone in urologic literature in that nearly five hundred pages is devoted to a subject which heretofore has been but lightly touched on in most books on urology. Its value to the obstetrician will be as great as to the urologist.

Revelation of Childbirth The Principles and Practice of Natural Childbirth By Grantly Dick Read M.A. M.D. Cloth Price 1/- 1s 1p 2/- London William Heinemann Medical Books Ltd 1942

Ten years ago the author published a monograph entitled 'Natural Childbirth' which created considerable discussion. The present volume elaborates the author's aims and methods and presents a record of some of his clinical results. The thesis expounded is that human reproduction is a normal natural biologic process. Pregnancy and labor should be conducted in this light so that they remain natural and unassisted. The pain associated with uterine contractions is the result of fear engendered by generations of ignorance, mis-conception and false teaching. We do not fear facts but doubts and uncertainties. The fear of parturition has become the great disturber of the neuromuscular mechanism of labor. Pain is caused by tension; tension is caused by fear. Tension leads to cervical dystocia.

If one accepts the theory that pregnancy and labor is a normal physiologic process which should be devoid of pain and that pain is the result of fear then the management of normal pregnancy and labor should include the elimination of fear. The author accomplishes this objective by education. His antepartum care includes the usual safeguards for the prevention of the hazards of childbirth and in addition a serious attempt is made to influence the mind of the patient. All efforts are directed toward impressing the pregnant woman to regard labor as a normal uneventful biologic process devoid of pain, discomfort and other pitfalls. Anxiety is removed by a careful explanation of all the facts which enter into a normal pregnancy and subsequent labor. Each antepartum visit drives home the fact that reproduction is normal and therefore uneventful. As an adjunct to this peace of mind which the healthy mother should develop she is taught to relax. Systematic exercises promoting physical relaxation is introduced at four or five months and continued to term.

Labor is conducted as naturally as possible. During the second stage the patient has access to an inhalation anesthetic which she can use at will but she rarely resorts to it. Thus, some analgesia is offered to her but her education is so complete that labor is an uneventful process. The pains that are associated with the final completion of the dilatation of the cervix are probably traumatic and should be relieved by firm rubbing or hard pressure on the sacrum. The relative anesthesia of the perineum which makes it possible for the author to repair superficial tears without anesthesia is probably due to the trauma to which the perineum has been subjected and not as the author would have one believe, the result of the excited state which the patient has achieved at the birth of the baby. Anesthesia is reserved for the abnormal or surgical delivery, in which real physical pain is due to laceration, excessive stretching and tension of the birth canal.

This small volume should be read by every obstetrician and student of the physiology of reproduction. No one can deny that emotional influences play a profound role in pregnancy and labor. It is true that pregnancy and parturition have become a pathologic state in the eyes of most physicians comparable to a major disease. It is equally true that few women in our large maternities deliver naturally. However, pain relief is here to stay even though the perfect analgesic agent has not been found. The author's argument that 'anesthesia in cultural labor is given primarily to satiate the escape demand of fear' will not deter the ever increasing widespread use of analgesia and anesthesia. In spite of the conversion of a physiologic function into a pathologic state pregnancy and labor have become increasingly safer for mother and baby. The hazards of childbirth are rapidly disappearing. Our women are restored to normal mental and physical vigor thereby often cheating them of extensive gynecologic reconstruction or a lifetime of invalidism. The spirit of the crusader is discernible in the declaration of the author "When as a lonely wanderer I first

set out to investigate the emotional influence of pregnancy and parturition it was the paradox of pain in a biological design that urged me on. For a year my professional life hung in the balance as pregnant women hurried by my door as scolded cats but in spite of all it is more satisfying to be nobody with something than somebody with nothing. This spirit should be admired.

The author dedicates this monograph to the late Joseph B. De Lee a fellow crusader in the interests of safer motherhood, for his kindly interest in his work and his personal friendliness and appreciation.

Constitution and Disease. Applied Constitutional Pathology. By Julius Bauer, M.D., Professor of Clinical Medicine, College of Medical Engineers, Los Angeles. Cloth. Price \$3.50. 1 p. 208 with 1 illustration. New York: Grune & Stratton, 1942.

The rapid advances in chemotherapy have brought a shift in the relative importance of those extrinsic pathologic factors, particularly infectious diseases, which until recently have held the center of the stage in producing human misery and death. For somewhat obvious reasons medical curriculums in this country have lagged in presenting the constitutional or hereditary factors involved in human pathology. This work by a prominent European clinician for many years professor of medicine at the University of Vienna is therefore particularly timely. Dr. Bauer states in his preface: "This little book may stimulate medical thinking and critical sense in evaluating old and new actual and apparent facts in medicine. It may help to promote good judgment and common sense in practicing medicine and in digesting current medical literature as well. It should be considered as a supplement to the routine medical curriculum. By virtue of these objectives it may contribute to the ultimate aim of medicine: to help the sick or as Trudeau used to say, to cure sometimes, to relieve often, to comfort always."

The author has drawn freely from his own clinical experience and from the medical literature in presenting facts illustrating the human hereditary complex. He has wisely avoided giving detailed family pedigrees but has emphasized the fact that predispositions often have an important hereditary background though the modus operandi of specific genetic factors may at present be unknown and has stressed the importance of this knowledge of heredity in the etiology of disease even where this knowledge cannot at present be used in treatment. In chapter III on constitutional biologic inferiority of organs and tissues much evidence is presented on the hereditary nature of defects, mental and latent involving specific organs and tissues. Chapters IV and V treat respectively the endocrine and nervous systems in their integrating roles and the interplay between these and the genetic constitution, the sum total of the genes and the phenotypic constitution, the human body and its component organs. The discussion is at points needlessly involved but the main thesis that the hereditary complex is primary and that endocrine and nervous relationships are secondary is sound. Chapter VI presents a critical evaluation of constitutional types and chapter VII deals with some major diseases with chiefly constitutional etiology. The inheritance of diabetes mellitus, obesity, constitutional hypertension, diseases of the hemopoietic system, peptic ulcer and cancer are discussed. A short concluding chapter touches on principles of treatment, nonspecific therapy and pitfalls and errors, particularly in endocrine diagnosis and therapy.

From the genetic standpoint the book is for the most part accurate. The author has correctly emphasized the importance of the study of uniovular twins, the pleiotropic or multiple effects of certain specific hereditary units or genes, and the variety of expression of given genes and gene combinations in different genetic (constitutional) and environmental (including therapeutic) backgrounds. The reviewer would criticize his interpretation of certain syndromes as due to linked genes rather than to the pleiotropic action of one gene in different genotypes and his ambiguous and unorthodox use of the terms dominant and recessive in connection with sex determination. The wise use of psychotherapy and the consideration of the constitutional background of the patient in diagnosis and treatment are stressed. This book will prove valuable to all who are interested in human biology and pathology but is recommended particularly to young practitioners and medical students. An extensive bibliography is included.

Do hiperhormoidismo e seu tratamento. Por Ulysses Tenorio Torres. Ilustrado de Clínica Médica da Faculdade Paulista de Medicina, São Paulo. 1942. 1 p. 342 with 13 illustrations. São Paulo: Empresa Gráfica da Revista dos Tribunais, Ltda. 1942.

The subject matter is arranged in sixteen short chapters. To each chapter is appended a selected bibliography and each reference is specifically quoted in the text. In the first four chapters the author reviews the embryology, histology and chemistry of the thyroid gland. The essential facts as we know them are briefly and clearly presented. One chapter gives a summary of the relations of the vitamins to thyroid function and reflects the popularity of the subject rather than any specific relation to thyroid disease. The next ten chapters are devoted to a discussion of hyperthyroidism, its general etiology, varied symptomatology, pathology and classification of types of the disease. Fifteen clinical reports are given in detail to illustrate these types and stages of the disease. Separate chapters are devoted to toxic adenoma and iodine hyperthyroidism. Typical clinical reports of such cases are included. The region around São Paulo is one of the world's important districts of endemic goiter, and both toxic adenoma and iodine hyperthyroidism are more common in endemic goiter districts. The author thinks that the distinction between toxic adenoma and toxic diffuse goiter is justified and should be attempted in every case despite the general accuracy of Wolff's dictum that "goiter plus symptoms equals adenoma and symptoms plus goiter equals Graves disease [toxic diffuse goiter]". The final chapter deals briefly but clearly with medical and surgical treatment. The author points out that the type and stage of the disease, also the social and economic condition of the patient must be taken into consideration in deciding on the best treatment. Certain types such as toxic adenoma or cases complicated by fibrillation or diabetes require operation at the first opportunity. Early or mild cases of toxic diffuse goiter should be treated in the first instance medically with rest, sedatives, vitamins, hormone preparations (estrogens and insulin mainly), iodine, bromine and quinine. He devotes several pages to a review of Kazarov's polyglandular hypothyroid treatment. Surgical treatment has the advantage of providing immediate relief in properly selected and prepared cases. This monograph is a well balanced, conservative summary of the subject and should serve a highly useful purpose for physicians who are familiar with the Portuguese language and who require more than the brief account in textbooks.

Practical Survey of Chemistry and Metabolism of the Skin. By Morris Markowitz, M.D., Associate in Dermatology and Syphilology, Graduate School of Medicine, University of Pennsylvania, Philadelphia. Philadelphia: F. & T. S. Co., 1942. 1 p. 196. Philadelphia: Blakiston Company, 1942.

The purpose of the author is to give to the student and practitioner of medicine a general survey of fundamental facts necessary for a better understanding of dermatology. In a concise and well organized presentation divided into part I on the chemistry of the skin, part II on hematology, part III on blood chemistry and part IV on vitamins in dermatoses we are given a better conception of the close relationship between internal medicine and related cutaneous manifestations. In spite of its small size the author has succeeded in covering an enormous amount of territory. For those who wish more complete information a well selected bibliography is found at the end of each section. The worth of the book could be improved by the addition of a few illustrations, especially where cellular pathology is concerned. Also closer attention to proofreading would eliminate several errors. The author is to be congratulated on giving so much in so few pages and strengthening the pattern of dermatologic thought which is attempting to place diagnosis on a firm basis of physicochemical changes rather than on long Latinic words and phrases. The book is highly recommended.

Recent Advances in Obstetrics and Gynecology. By Aleck W. Bourne, M.A., M.B., B.Ch., Obstetric Surgeon to St. Mary's Hospital, London, and Leslie H. Williams, M.D., M.S., F.R.C.S., Obstetric Surgeon to Out Patients, St. Mary's Hospital. Fifth edition. Cloth. Price \$5.00. 1 p. 483 with 72 illustrations. Philadelphia: Blakiston Company, 1941.

Most significant in the discussions in this volume are the chapters on sex hormones, ovarian tumors and the uses of roentgenology in obstetrics. Especially worth while is the discussion on cancer and the excellent results now achieved by early diagnosis and proper treatment. Special emphasis is placed on the development of postpartum care to a status resembling that of antepartum care.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

GENETICS OF HUMAN CANCER

To the Editor—What is the present opinion as to heredity in the transmission of cancer from parent to offspring? Is it a dominant mendelian characteristic? Is there any evidence besides that of rats that this tendency is inherited? If so do the same kinds of cancers occur in the progeny as in their forebears? Does this heredity factor vary in different types of cancer? What recommendation would you give to a person contemplating matrimony with a person one of whose parents has been a victim of cancer?

Lieutenant M C A U S

ANSWER—The genetics of human cancer are too unknown, too complicated, to discuss dogmatically at the present time. Certainly some rare malignant growths, as for example malignant glioma of the retina or the less malignant neurofibromatosis, have a strong hereditary background. But for the common types of carcinoma the evidence is for the most part not clear as to just what influence heredity has, and for that matter the genetic pattern of cancer in mice and rats is far from clear, with nongenetic factors coming into play in some of them. Certainly multiple polyposis of the colon with its common malignant change is a familial disease at least in some instances, but to say that carcinoma of the colon is ordinarily on a hereditary basis would be going much too far. There is some statistical evidence that cancer of different organs tends to occur more frequently in persons with relatives with cancer in the same organs than in those with no such relatives, but the evidence is slight indeed and certainly shows no pronounced influence of heredity in the production of cancer. As to recommendations concerning matrimony with a family history of cancer, there should be no hesitation in the case of a person who has had one parent a victim of cancer, unless the cancer was one of those rare cases of glioma of the retina, neurofibromatosis or one of the few other neoplasms with a strong hereditary background. If there has been cancer in both sides of the family involving the same or equivalent organs consultation with some one familiar with the genetics of cancer is to be recommended.

DYSCHONDROPLASIA

To the Editor—I have a patient with dyschondroplasia. Is there any treatment that may be of benefit? The parents will allow the child to be placed in an institution for research purposes.

J. Lewis Fretz, M.D., Seattle

ANSWER—There is no treatment for dyschondroplasia which offers any hope of improving the condition. Both vitamins in varying amounts and mixtures and preparations of the glands of internal secretion have been used without any definite evidence of benefit. This is a condition which is probably due to a primary germ cell defect and as such offers little hope of improvement as the result of therapy. One of the Shriner hospitals for crippled children or an orthopedic service in connection with one of the medical schools would probably be willing to accept this child for care.

BREAST NURSING AND GALACTAGOGUES

To the Editor—A woman aged 41 had her first baby recently, but she does not have enough milk for the baby. What is the best preparation to give the mother to stimulate the secretion of milk? What about vitamin B complex or glandular preparations?

M.D. Oklahoma

ANSWER—Specific galactagogues, whether in the form of food or of drugs, are no longer advocated. Heredity is an important factor; the ability to nurse is commonly transmitted from mother to daughter. The nervous or mental condition of the mother is an important factor in her ability to nurse. Plenty of rest, calm environment and moderate exercise are advisable. A well balanced diet containing about 1 quart of milk daily and total fluids of 2 quarts is advisable. The real stimulus to milk secretion is thorough emptying of the breast. If the baby fails to empty the breast, this should be done by manual expression or a breast pump.

PROBABLE RENAL COLIC FROM STONE AND DIAPHRAGMATIC PLEURISY

To the Editor—On July 13, 1942 a laparotomy was performed on a man aged 34. Early symptoms at the onset of his illness two days earlier were suggestive of the urinary tract with pain in the right costovertebral angle referred down around the flank with extension to the back of the penis. He had dysuria with frequency but the urine appeared clear amber even though it contained 5 red blood cells per high power field. The urine was otherwise negative. The white blood count was 8,800. When the abdomen became rigid on the second day operation was performed. The appendix was long, fibrosed and not acutely inflamed. The left and right kidney were fused on the right side with the right kidney pelvis facing outward and backward to the right side. A retrograde pyelogram showed that the left ureter entered the bladder on the usual left side and extended upward across the midline to the left kidney fused to the lower pole of the right kidney. This kidney pelvis faced normally to the midline. There was only slight hydronephrosis of the right (upper) kidney pelvis. The appendix was removed but severe tenderness remained over the large kidney mass. The postoperative temperature ranged from 99 to 101 F. until the tenth day at which time the tenderness had completely subsided. On his first day out of bed the patient suffered from a severe continuous pain in the left costovertebral angle not relieved by morphine. The chest was clear, the gastrointestinal tract was normal, the patient voided small amounts of normal urine every forty-five minutes. The urinalysis showed a trace of albumin, an occasional white blood cell and a rare red blood cell. The left costovertebral angle was not tender. The pain began to subside after three days but was still evident to the patient two weeks later as a soreness. With the onset of this pain the temperature ranged from 101 to 103 F. The patient was discharged from the hospital on the twenty-first day after operation and two days after a retrograde pyelogram was done. About four or five days after this a severe left costovertebral angle pain developed and the patient began to have occasional deep involuntary respiratory inspirations that would begin with a yawning action. These occurred only two or three times each day while the patient was in the hospital but after he was home they increased in frequency until they occurred as many times as eight in one hour. These were more prone to occur when the patient was sitting. He had no control over them whatever and said that he would start to yawn and would then get a feeling as if some one was giving him artificial respiration only the reflex muscle action was always inspiratory. There was never a succession of such involuntary acts. Between the fifth and sixth week after operation these involuntary inspirations began to occur more frequently on walking. During the sixth week he had more dyspnea on walking up a flight of steps than he had had before and certainly more than his inactivity would produce. During the seventh and eighth weeks both the dyspnea and the involuntary inspirations began to diminish and become less frequent. Now these involuntary inspirations occur only two or three times each week. I would be interested in getting an opinion on these involuntary inspiratory spasms and also some idea as to the cause of the severe left costovertebral pain while in the hospital since there is no kidney in that area on this patient. He is not of a neurotic nature. He is a steel welder.

M.D. Pennsylvania

ANSWER—This is an interesting presentation but unfortunately does not give all the information one would like to have in order to make a definite diagnosis. However there are several points that stand out clearly and forcefully. In the first place the original attack that the patient had can be called a renal colic due to stone. The inference that the patient had a renal colic due to stone is based on the sudden onset of pain in the right costovertebral angle referred to the back of the penis associated with dysuria and frequency and the presence of red blood cells in the urine. The white blood count was 8,000 which is compatible with renal colic. The retrograde pyelogram disclosed a slight hydronephrosis of the right kidney pelvis. The patient was operated on and an appendectomy was performed. The reason for this is not clear from the evidence presented and from the symptoms mentioned. At operation the appendix was found to be not acutely inflamed. Following the operation the patient had a temperature that varied from 99 to 101 F. which was associated with frequency of urination, albumin, red blood cells and white blood cells in the urine. This is compatible with an acute pyelitis following the operation. This part of the query seems perfectly clear.

With regard to the respiratory inspirations that began with a yawning action associated with dyspnea on walking up a flight of stairs this sounds without a physical examination and without more evidence like an attack of diaphragmatic pleurisy. Another possibility to consider is the fact that the patient may have had a little hiccup but nothing is said about this.

The third point raised is the presence of left costovertebral pain while in the hospital. The correspondent wishes an explanation since there is no kidney in this area. The left costovertebral pain may well be explained on the basis of a diaphragmatic pleurisy or intercostal neuralgia or neuritis or perhaps something in the spinal cord itself. It is exceedingly difficult to venture an opinion on the latter subject. It is noted that the correspondent states that the patient is not of a neurotic nature. This does not appear to be a neurosis in any sense of the word.

DISPOSAL OF OLD X RAY FILM

To the Editor—I am interested in a way to dispose of old x ray films. Can you please suggest a method? Is there a collector for such films? I am a doctor's secretary and have been asked to dispose of some old films. I am under the impression that the chemicals coating the film are of some value in these days of conservation. Gertrude Fischer New York

ANSWER.—Old x-ray films can be readily sold for scrap, and the price paid per pound is fairly high at the present time. There are numerous jobbers in every city who will purchase the films, and the local chamber of commerce can be of help in making the selection of the best buyer. The classified section of the telephone directory may give a list of buyers, but usually the roentgenologist's mail contains numerous advertising letters and postal cards from individuals anxious to purchase scrap film. One should be careful to check the weight of the films and should obtain several quotations before selling.

SUBSTITUTES FOR RUBBING ALCOHOL

To the Editor—The recent withdrawal of rubbing alcohol from sale except on the prescription of a licensed physician has brought up the question as to whether there is any solution that might be substituted for alcohol for that purpose. Can you tell me where I can obtain any information on this subject? William R. Darr, M.D. Phoenix Ariz

ANSWER.—Isopropyl alcohol as included in the following formula has been used as a substitute for ethyl alcohol as a back lotion: isopropyl alcohol 25 cc, glycerin 10 cc, acetate acid 4 per cent 25 cc and sufficient water to make 100 cc. Coloring and perfume may be added. A number of noninjurious emollient cream type body lotions and nongreasy skin oils that can be used as a substitute for rubbing alcohol are offered by several of the reputable pharmaceutical manufacturers.

SLEEP DISTURBANCES OF INFANCY AND CHILDHOOD

To the Editor—Many parents complain that their child will not sleep at night, the child otherwise acts perfectly normal with no crying, fever or vomiting but just refuses to sleep. Many will say that the child sleeps little during the day. I have carefully checked these children and found nothing essentially wrong, the increasing of the formula and the addition of sedatives have been of little value. I should appreciate your suggestions as to how to combat this problem.

Joseph A. Concello M.D. Chester Pa

ANSWER.—There is a considerable variation in the sleep needs of infants and children. Many children require large amounts of sleep, while many others are perfectly happy and healthy on limited hours of sleep. There is no fixed number of hours that an infant must sleep.

Disturbances of sleep during the early months of life are usually due to physical causes such as hunger, colic, soiled diaper, the pain or itching of ammoniaical dermatitis or over-distention. Parental agitation also has an adverse influence on sleep during early infancy.

After the sixth month psychological factors become more important. Sleep disturbances have their origin in a generally improper attitude toward the child and are rarely isolated symptoms. Other behavior problems are usually associated.

The best prophylactic against sleeping difficulties is a regular schedule rigidly adhered to. There should be no irregularity in the hour of retiring. Attention should be given to the following features. The habit of going to bed quietly should be established at an early age. There should be no rough, boisterous or exciting play late in the afternoon or early evening and no loud radio programs or undue excitement before bedtime. It is desirable to have a preparatory quiet period before attempting to go to sleep. The hour before bedtime should be a calm and happy one. No punishment should be meted out just before or at bedtime. Going to bed should mark the end of activity. Once a child has gone to bed, all bids for attention, as requests to go to the toilet, for water, to kiss goodnight again, should be ignored. The parent should not remain with the child until he has gone to sleep. If possible the infant or child should sleep alone in a room in which the temperature, ventilation and humidity are properly regulated. He should not be too hot or too cold. The room should be sufficiently isolated so that sounds from other rooms will not readily be heard, but it should not be necessary for adults to tiptoe about the house, as the infant must become accustomed to sleeping through a moderate amount of noise.

A warm beverage or a warm bath just before bedtime often helps to relax the child. However, once an undesirable sleeping routine has been established, the only method of cure is to allow the child to cry himself to sleep for a week or more if necessary. Each night he will cry for a shorter period until finally peaceful sleep ensues.

EPILEPSY ASSOCIATED WITH MENSTRUATION

To the Editor—A married woman aged 29 has frequent petit mal like seizures in which she loses consciousness for a second or two, drops what she is holding and jerks her hands a little. This is about all that occurs as I have seen several of them. She was perfectly normal until catamenia at 12 years, when the attacks began to occur with each menstrual period never missing one. In the interim she was quite well and free from attacks. On several occasions during a period she has had grand mal attacks and recently has had quite a few petit mal seizures between periods. The periods are scanty, lasting only three or four days but otherwise are normal. At 14 years an air encephalogram was done by a well known neurosurgeon (now deceased), which apparently revealed no pathologic condition and gave no relief although he suggested doing some sort of brain surgery from an occipital approach (decompression?). During her one pregnancy she was entirely free from attacks which returned three weeks after the delivery. Her physical examination other than for moderate obesity is entirely normal. There are no signs of increased intracranial pressure or meningeal irritation. All laboratory work including blood counts, urinalysis, blood sugar and basal metabolic rate is normal. The patient has been told by doctors that a bilateral oophorectomy will cure the trouble and she wants me to do this as she has had no relief from either phenobarbital or phenytoin sodium in adequate amounts. The effect on her nervous system is already considerable. Assuming the results of a lumbar puncture which I shall do in a few days are negative do you think the possibilities of a cure justify an oophorectomy? Have you any other therapeutic means to suggest? If oophorectomy has been done in similar cases, what has been the result? M.D. Washington

ANSWER.—Rarely are a patient's seizures so definitely related to the menstrual function. Nevertheless there is no reason to believe that oophorectomy would lessen her seizures, and the operation undoubtedly would increase her physical and psychologic problems of adjustment. This operation apparently has not been reported in recent years. Older case reports are unconvincing (Ashe J S. *Dublin J M Sc* 4 142 [May 20] 1920. Everke, C. *Monatschr f Geburtsh u Gynak* 61 256 [Jan] 1923). Spratling, in his book published in 1904, stated that he observed improvement in 2 of 9 patients operated on. Even in patients with migraine, in which condition cessation of attacks at the time of menopause is the rule, artificial menopause is usually without benefit. Therefore oophorectomy is no more indicated than is occipital decompression, suggested fifteen years ago, designed to provide a freer flow of blood from the brain. The experimental use of theelin or other estrogenic substances would be preferable to the use of the knife. An electroencephalogram would be helpful in judging the severity of the case. If this examination should confirm the clinical diagnosis of petit mal, there is a good chance that these attacks will gradually disappear spontaneously. For the grand mal, a combination of phenytoin sodium, to the limit of tolerance, and of phenobarbital may be used.

AMPHETAMINE INHALATIONS AND CORONARY OCCLUSION

To the Editor—In *Queries and Minor Notes* in *The Journal* Sept 26 1942 page 325 there was an inquiry regarding the advisability of using amphetamine for a patient with a recent coronary occlusion. In answer to the inquiry it was stated that the consultant to whom the question was referred had observed no instances in which amphetamine appeared to have any effect on the coronary vessels, and it was stated that the drug might be used safely for inhalation by patients who had had a coronary occlusion. In view of these statements, I should like to call attention to the experience of 1 of my patients. This man had allergic rhinitis and had acquired the habit of using the amphetamine inhaler frequently. On Feb 16 1942 he purchased a new tube of this material and used it at intervals of a few minutes throughout the afternoon and evening. He felt bad and had a sense of 'heaviness' throughout his body when he retired at 10 30 p.m. About 2 a.m. he was suddenly awakened by a sense of oppression in the precordium and great pounding of his heart. These symptoms lasted several minutes. After they were over, he was extremely weak and noticed tingling in his arms particularly the left. The next day he was quite short of breath and again had tingling in his arms with even slight exertion. He did not consult me until two weeks later but during this interval he was constantly short of breath and had numbness and tingling in the arms on the slightest exertion. An electrocardiogram taken at that time revealed normal mechanism, regular rhythm and a T wave poorly deflected in all leads. No formal diagnosis was made but it was suggested that this picture might be the result of debilitating disease, asthma or any cause, obesity or the like. He was kept in bed several weeks and the symptoms described disappeared. The electrocardiograms taken after the rest period showed some changes from the previous electrocardiogram. The rate was 80 instead of 72 and the T wave was poorly deflected in all leads. R₁ was short and the configuration of S₁ suggested a coronary occlusion. These electrocardiograms were interpreted as not normal but not entirely characteristic of coronary occlusion. Although the symptoms were not in every way typical of the onset the conclusion is that this patient had a coronary thrombosis. Whether the amphetamine inhalation had anything to do with precipitating the occlusion is difficult to determine at this time. The patient himself feels definitely that it had.

EDUCATION AND THE WAR

EDWARD C ELLIOTT, LL.D.

Chief Professional and Technical Training
War Manpower Commission

WASHINGTON, D C

Certainly any thorough discussion of education and the war would require more time than has been allotted to the present speaker and more patience than is possessed by the present listeners. Consequently I and also you must be content with a brief and sketchy interpretation of the educational scene as I have observed it, particularly during the past six or eight months. My attention will be focused on the portions of the scene that have a war relation to the institutions ordinarily classified as higher institutions—colleges, universities and professional and technical schools.

Since the days when the dark clouds of war began to gather on the national horizon, American schools from the lowest to the highest have exhibited an energetic anxiety to give conclusive proof of their loyal usefulness as instruments for the increase of the national might demanded for victory. Teachers and students, day by day, have stood fast, as minute men, ready to respond instantly. There is not a community anywhere in the country that is not indebted to its schools for giving new reality to the lessons of public service. Every program designed to arouse and to unify the people has turned to schools for help, and that help has been given without stint.

Today all the people are being matriculated in the College for War. The struggle for human freedom has packed the words labor, learning and liberty with new meanings. These meanings constitute the assigned lessons for millions, and these lessons are not easy. We who thought of ourselves as an educated nation now realize the essential difficulties of educating the educated, of educating for war those who have long been habituated to the ways of peace, of training those concerned with self interest so that they become more concerned with the survival of the ideals of the nation.

For the first time we of the United States are faced by the grim facts of the scarcity of the things needed for the victorious battle. We now know as never before, that our resources of nature and of manpower are limited and that these resources must be mobilized with skill and foresight and allotted with yet more skill and more foresight. New rules must be accepted and practiced if we are to escape famines—famine of metals, of munitions, of machines, of money, of medicine, of food and of fuel, and above all famine of trained manpower. Teaching has become a critical

war occupation. The teacher in areas of war technology has become as necessary as tanks and torpedoes.

My connection with the War Manpower Commission began last June. Then I assumed responsibility for what was known as the Division of Technical Employment and Training. This division, according to a particular administrative order, was charged with the following special duties:

- 1 To review the organization and operations of the Engineering, Science and Management War Training Program of the Office of Education to insure effective utilization of the higher, technical and professional institutions for the training of personnel needed for the armed forces, for essential industrial and agricultural production and for governmental services.

- 2 To direct the activities of the National Roster of Scientific and Specialized Personnel through the head of that office to insure the proper discharge of responsibilities for the development of information as to the qualifications and availability of professional and technical workers for the armed forces, war industries and governmental war activities.

- 3 To direct the activities of the Office of Procurement and Assignment through the head of that office to insure proper discharge of responsibilities for the recruitment of physicians, dentists and veterinarians for the armed forces and for essential civilian purposes.

- 4 To be responsible for the coordination of the work of the various agencies and offices under his jurisdiction and for the elimination of any duplication.

- 5 To recommend to the director of operations, for execution in various regions, such action as may be necessary to secure adequate training, classification, employment transfer and placement of professional and technical workers.

- 6 To establish effective working relations with the regional offices of the War Manpower Commission so as properly to advise and to counsel the regional manpower directors on specific problems in their regions relating to the training and employment of professional and technical workers.

- 7 To assemble current information as to the functions, programs and activities of the several administrative divisions of the War Manpower Commission having relationship to the training and employment of professional and technical workers, consulting with the heads of such divisions to arrive at a common understanding of the scope of activities of each division.

- 8 To establish and maintain effective relations with other governmental agencies concerned with the training and employment of professional and technical personnel essential for the national war effort to promote general acceptance of the program and policies of the War Manpower Commission.

9 To establish and maintain such relations with the higher educational institutions, and with the associations representing those institutions as will increase their usefulness to the national war effort

Truly a heavy requisition for a staff which most of the time consisted of myself and one clerical assistant. Whatever the limitations of accomplishment it has been my principal duty to be concerned with the training and the supply of professional and technical personnel. Modern warfare makes heavy and heavier demands on these sections of our manpower. We know that we have an insufficient supply of physicians, of engineers, of chemists, of physicists, of scientific research workers and of other specialized technologists requiring prolonged training. What proportion of this supply shall be allotted to the armed forces, to the war industries and to the maintenance of essential governmental and civilian activities? What plans shall be followed to step up the production of these critically important workers?

At best it must be admitted that we have proceeded in an uncertain, catch as catch can fashion. If the war is not to be too prolonged, we shall muddle through. On the other hand, if the war is to continue for three, four, five years, then we may be self convicted of short sightedness for not devising formulas for a better balance of supply and needs and for not insuring a continuous flow of trained men and women for the essential service of a nation at war.

Two months ago the War Manpower Commission effected certain internal reorganizations and reallocations of responsibilities. The activities of the commission were divided among five bureaus—Selective Service, Placement, Program Planning and Control, Training, and Labor Utilization. Thus the division with which I have been connected became the Division of Professional and Technical Training within the Bureau of Training. All matters relating to employment were assigned to the Bureau of Placement. To this bureau went the National Roster of Scientific and Specialized Personnel and the Procurement and Assignment Service.

Here may I digress for a moment and express the rare personal satisfaction I have had from working with Dr. Frank Lahey and his associates on the directing board of the Procurement and Assignment Service with Commander Lapham and with that dynamic stimulator of the minds and actions of men, Dr. Morris Fishbein. From these lamps of medicine my own feeble candles have been kept lighted. I have been permitted to see something of the mighty strength of the professions of medicine and dentistry and to have a new understanding of their problems and their lacks.

At the present time the Division of Professional and Technical Training is chiefly concerned with the following:

1 Serving as a liaison for the War Manpower Commission with the War and Navy departments, with special emphasis on the utilization of the colleges, universities and technical schools for the several forms of special training needed by the armed forces. During recent weeks three members of the staff of the division have acted as members of the joint committee, representing the Army, Navy and War Manpower Commission, established for the selection of nonfederal educational institutions to be used by the Army and Navy in connection with the specialized training pro-

grams. It is estimated that these programs will involve the training of approximately 300,000 young men during the coming year.

2 Promoting ways and means for increased attention to training through higher educational institutions in the various professional and technical fields—engineering, medicine, physics, pharmacy, chemistry, mathematics, nursing, teaching—with special reference to the needs of war industries and of essential civilian activities. This has emphasized the importance of knowing far more accurately than at present the quality and quantity of these needs. At the present time surveys of these needs are under way by governmental agencies and by industrial and professional organizations.

3 Continuing the organization and stimulating the activities of consultative committees representing the various professional and technical groups. These committees are concerned with maintaining the supply of trained personnel for the direct as well as for the indirect needs of the war effort. This has meant that considerable attention has been devoted, and continues to be devoted, to the formulation of policies for the deferment, under the Selective Service System, of students in the fields of critical scarcity.

May I append to this crude and wholly inadequate sketch a brief observation or two as to the future, immediate and remote.

Twenty or more years ago I was led to call attention to what I characterized as the struggle then going on in the world for the possession of the minds and the ability of youth. It was my conclusion that the group, the class, the nation succeeding in gaining control of the most of the best of its youth would control the fate of civilization. The happenings throughout the world during the past two decades—especially in Europe—furnish tragic evidence of the outcome of this struggle. Time and circumstance do not permit discussion of this phenomenon in the life of modern mankind. Nevertheless, it is relevant to my subject to call passing attention of the present day struggle for youth going on in our midst. This promises to lead to decisions of far reaching importance as the nation strives to mobilize its full battle strength.

At its meeting on July 29, 1942 the War Manpower Commission considered at length the place of the colleges and universities of the country in the manpower problem. A special committee was appointed to examine into this matter. The report of this committee was presented to, and approved by, the Commission on August 19. This must be regarded as a declaration of national policy as to the youth now in our higher educational institutions and to the youth who will be in these institutions during the period of the war.

In view of the problems presented to all of the so-called professions, it is well to be reminded of one significant position of this declaration of policy.

"All able bodied male students are destined for the armed forces. The responsibility for determining the specific training for such students is a function of the Army and Navy."

Under the inexorable demands of the battle fronts this policy is now being implemented. The effect of such implementation on national life and efficiency may be only roughly forecast. Without question the impact will be painfully felt by all professions. Whence will flow the stream of trained men and women essential for the maintenance of life back of the armed forces? I

leave this question as one which is yet unanswered but must be answered if we are to escape disasters of our own making

Eight months of experience in Washington have impressed on me the tremendous difficulties in the formulation and application of plans for the best use of education for the purposes of the war. Not the least of these difficulties is the lack of agreement among those who speak and act for education. Education too often does not appreciate the inescapable requirements of global war, and those seeking to fulfil the requisitions of war are not inclined to recognize the limitations and contributions of education. However, in spite of confusions, delays, mistakes and the conflict of prejudices, there is today much encouraging evidence that the rightful place of education in the war power pattern of the nation is becoming clearer. Meanwhile men of sense and responsibility must assume the trying task of arbitrating between those who persist in seeing education in peace time terms and the extremists—and, believe me, there are many of these—who would close all the institutions of higher education for the duration.

In the making of the decision, it must never be forgotten that the American youth involved represent our chief hope of attaining peace in the world—a peace that will never again find the nation unprepared for war, as it was twenty-five years ago and once more on Dec 7, 1941—a peace with power to maintain peace among men and nations. Such I consider to be the great task of education and the war.

PREMEDICAL AND MEDICAL EDUCATION AS RELATED TO THE UNITED STATES ARMY

BRIGADIER GENERAL JOE N DALTON

Assistant Chief of Staff for Personnel Services of Supply
WASHINGTON, D C

An invitation to address the Annual Congress on Medical Education and Licensure is a privilege laymen do not ordinarily receive. Consequently, as I reviewed the program and noted the qualifications of the speakers, the thought occurred that perhaps I was invited as an antidote. I accepted the invitation with the belief that I could help the members of the congress understand some of the Army's educational problems and the hope that the Army might thus receive still further aid from the medical profession.

My father practiced medicine and surgery in Winston-Salem, N C, for many years, and if you will accept my deep respect—my affection—for your profession as a substitute for medical training, we can perhaps find more common ground and more mutual interests than might first be supposed.

Our goals are similar, although the fields in which we work are different. Physicians were the original trained personnel managers, and a physician's interest in his patient transcends the specific treatment he administers. As assistant chief of staff for personnel of the Services of Supply, my responsibilities as well as my interests are primarily with respect to people—how they can best be

used in the Army—people as individuals—groups of people—what is best for the man at any given moment and what fits best into the long range picture.

We have yet another common group in that physicians were among the first to realize that education is a continuous process. It does not stop at any age nor does it end on the receipt of any academic degree. Physicians, therefore, possibly to a greater extent than any other professional group are vitally interested in the Army's specialized training plans to provide trained skilled men to meet Army needs.

I followed the customary educational lines of a man interested in the Army as a career. I thought my formal contacts with education had ended after receipt of a degree from Virginia Military Institute and additional work at the University of the South and the various Army schools which I attended. Within the past few months, however, I have found myself in the center of as interesting and as important a series of educational problems as have ever developed in this country.

It became possible to develop a long range, sound program for the utilization of educational facilities when Congress lowered the draft age to 18. It became apparent, also, that the Army would have to assure itself of an uninterrupted flow of the kinds of specialists which had been provided by colleges and universities. The Secretary of War assigned the responsibility for the development and operation of Army plans for maintaining the flow of these specialists to General Somervell, commanding general of the Services of Supply, and my immediate superior. As a result, an Army Specialized Training Division has been created under my supervision, and I have appointed Colonel Herman Benkenra, formerly head of the Department of Economics Government and History at the United States Military Academy, director of the new division.

The Secretary of War stated the objective as follows:

The objective of the plan is to meet the need of the Army for specialized, technical training of soldiers on active duty for certain Army tasks for which its own training facilities are insufficient in extent or character. To that end the Army will contract with selected colleges and universities for the use of their facilities and faculties in effecting such training of selected soldiers in courses prescribed by the Army. This plan will enable the Army to make selections for this training of qualified young men on a broad democratic basis without regard to financial resources.

Army needs include soldiers trained as physicians, dentists, veterinarians, engineers, physicists, mathematicians and experts in rare languages.

In every field with which the Army is concerned we have called on civilian educational experts for counsel as to curriculums and as to methods of selecting men to be assigned to this program. In the case of the medical profession General Magee and his staff are guiding our work and selecting civilians with whom consultations are held. We recognize that the physicians must be satisfied with the training the men in medicine receive and I assure you that there is no thought in our minds of shortcutting any of the essentials of medical education. We do expect of course that every possible means will be used to compress the periods involved in training.

The Army specialized training program must provide men trained in two broad fields—medical including dentistry and veterinary medicine, and technical, including engineering physics chemistry and psychology.

In the medical program, the training is for a degree, as there is no such thing as a partially trained physician. The high standards required by the medical profession must be maintained.

In the technical program the training is not for a degree but is pointed to what might be called Army requirement standards. The technical program has been compressed by increasing the work load and by eliminating work in subjects not required for performance of the Army tasks for which the men are being trained.

Soldiers assigned to the Army specialized training program will be on active duty as members of a unit located at a college or university. They will be under the direction of a commandant, who will be responsible for discipline and control. They will be in uniform, and they will receive the pay and allowances of enlisted men as provided by Army regulations. Housing, feeding, instruction and other services will be provided by contract between the institution and the Army.

These soldiers will rise at 6:30, and from then until taps at 10:30 that night, their day will be as rigorous as it was during the basic military training period. A typical week will include twenty-four hours of academic classroom work, including laboratory periods, and twenty-four hours of supervised study time. In addition there will be six hours a week of supervised physical conditioning and about five hours a week of military instruction, which will consist of lectures, orientation work, morning formations and some drill. Neither the physical nor the military instruction will require outside preparation. Their purposes are to maintain the physical condition of the men and to refresh their minds on military subjects and information. There will be sufficient free time provided each day for personal affairs, and the men will be off duty from late afternoon on Saturday until the Sunday evening meal.

The Army program is based on a series of twelve week terms. This decision was reached after study and consultation with civilian educators because it is the shortest period in which satisfactory curriculums can be prescribed, and therefore the most flexible time period which the Army can use.

In addition to the Army need for a flexible program from the standpoint of variations in curriculums, there is an even greater Army need with respect to starting dates of the various specialized training programs. To be specific, some colleges will be asked to initiate programs on March 1, others on April 1, still others on May 1, and so on. Only in this way can men be assigned to colleges for Army specialized training as they become available through replacement training centers and induction centers. The alternative is the loss of valuable men who should be working under this program, but who, if they cannot be assigned promptly to an institution, are assigned to troop duty or overseas service. This does not mean, of course, that any one institution will be expected to take new units for training more frequently than quarterly, although some institutions have already demonstrated the practicability of taking more frequent assignments of soldiers.

The twelve week terms are combined into a basic program and a series of advanced programs.

The basic program consists of three twelve week terms or a total of approximately nine calendar months. For the most part, all men entering at the basic level

will undergo the same instruction during the first of the basic terms. In the second and third terms, variations begin to occur, depending on the interests and abilities of the respective men. A typical curriculum will require about two thirds of the contact academic hours in mathematics, physics, chemistry and other sciences, and the remaining one third will be devoted to history, English and geography.

Men who qualify for advanced work will at the conclusion of the basic program be routed into specialized fields.

Here again the work is in twelve week terms, but the number of such terms is dependent on the field in which the soldier is working and varies accordingly.

The problems involved in selecting the institutions which will provide this academic training are most important, and a joint board consisting of three representatives of the Army, three of the Navy and three of the War Manpower Commission is working on them. The board's problems are to determine the best possible use of educational facilities and to minimize overlapping and overconcentration in any one institution or in any one area. Wherever possible, only one of the services will be located at an institution, in order to avoid administrative difficulties. We do not know at this time how many institutions will be used, but we do expect to start with the best institutions in each field and work outward from that nucleus, with due consideration to geographic questions.

How, then, does this program differ in the case of medicine?

The premedical program runs five terms, or sixty-four weeks of elapsed time, as compared with the three term basic technical program. The curriculum calls for the following work, which has been translated into semester hours: mathematics, 8, physics, 8, chemistry, 18, zoology, 12, history, English and geography, 15, and other selected subjects, such as languages, sociology and psychology, 25. This is a total of 86 semester hours.

Premedical students will be housed in the same manner as other soldiers in the basic training program, will be subject to the same discipline and will undergo the same amount of military training and physical conditioning.

The medical program calls for the same number of semesters of work as medical standards now require. The compression here is one of eliminating long vacations and limiting furlough time to about four weeks in each calendar year.

Medical curriculums are unchanged. Each school will continue to establish its own curriculums.

Medical men assigned to this program will be selected in about the same manner as medical students have been selected all along—from the premedical group. School authorities will be requested to do the selection job under the general supervision of the Army, as these men are, after all, soldiers.

Military training will be reduced to one hour a week, and physical conditioning will be left largely to the men to work out for themselves. Wherever possible, the men will be housed and messed similarly to other men assigned to the Army specialized training program. When this is not possible, commutation allowances will be granted and the men will make their own arrangements for board and room.

It is planned that on graduation men will be commissioned as first lieutenants and then placed on inactive status so that they may complete a year of internship or residency.

One of the most important questions is obviously the one of selection of men. Where are they coming from? How will they be selected and assigned?

Let us assume that we shall be able to meet the problems of the transition period in a satisfactory manner and confine the discussion at this time to the long range picture, beginning with a young man graduating from high school and being inducted in the Army shortly after his eighteenth birthday.

While this soldier is undergoing his basic military training he will be under close observation by his superiors and in addition will be given tests to indicate his capacities and potentialities. These tests will be devised according to customary testing practices, which, of course, involve aid and assistance from people of such specialized fields as medicine.

Military training records, academic records and testing scores of all men who attain a score of 110 or higher on the Army general classification test will be coordinated by screening and selection boards. These boards will review the various records and, after a personal interview with each candidate, will recommend appropriate action. Men of sufficient maturity who meet all other qualifications will be directed to officer candidate schools. Those who are potentially good officer material but who need maturity and those who also need further academic training will be assigned to the Army specialized training program.

Throughout the program there will be constant screening of all soldiers working under it. Screening boards will be established at each institution where an Army specialized training unit is located, and at the end of each term men who are qualified will be continued in the next highest level of the program until their work has been completed. At that time they will be recommended to officer candidate schools.

Some men will be qualified for officer candidate schools at the conclusion of the basic program. Some men, unfortunately, will fail to attain required minimum standards and will be returned to troop duty. Some men will qualify academically but will fail to meet other Army standards. They will be returned to troops as enlisted men.

It is obvious that we shall need not only counsel but active assistance from members of the medical profession in all screening and selection processes of the medical program. We also need the help of your profession in the screening and selection processes in the other phases of the Army specialized training program. Some physicians will be asked to become members of the selection and screening boards at replacement training centers and others will have the same request made with respect to units at specific institutions. The Army knows what it needs, and among those needs are the wholehearted support and assistance of the members of the medical profession throughout. This we know we shall receive.

I earlier touched on the point that education is a continuous process, and in these few minutes I have tried to start your education with respect to the Army specialized training program. Now you must educate us so that the medical profession and the Army can together fill the Army's medical needs.

MEDICAL EDUCATION AND THE PROCUREMENT AND ASSIGNMENT SERVICE

HAROLD S. DIEHL, M.D.

Member, Directing Board, Procurement and Assignment Service,
Dean of Medical Sciences, University of Minnesota

MINNEAPOLIS

The Procurement and Assignment Service, which might now be called the medical division of the War Manpower Commission, is the agency of the federal government responsible during the war for the allocation of physicians, dentists and veterinarians to meet the needs of both the armed forces and the civilian population. Obviously, one of the major concerns of such an agency must be with the medical, dental and veterinary schools, which serve as the only source of supply for additions to and replacements within these professions.

The importance of maintaining and, if possible, of increasing the supply of physicians was recognized at the beginning of the program of national mobilization and military training. The medical schools responded promptly to this need by recommending through their national association that the graduation of physicians be accelerated by the discontinuance of vacations and that medical schools increase their enrolments as much as their facilities would permit without prejudice to the quality of medical education. Recently, they have gone still further in shortening the over-all period of medical training by recommending that medical schools reduce their requirements for admission from three or four years to two years of premedical college work.

MAINTENANCE OF ADEQUATE TEACHING FACILITIES

Since our involvement in the war, medical schools have released many of their faculty members for service, in many instances highly specialized service, with the armed forces. At the same time, they have assigned other members of their staffs to work on war research. The medical schools have done all this promptly and willingly, in spite of the fact that they are faced with their heaviest teaching responsibilities in history.

The concern of the Procurement and Assignment Service with this recruitment from medical faculties is to assure the retention of adequate teaching staffs for the conduct of a sound program of medical education during the war. To accomplish this, each medical school has been requested periodically to appraise its teaching faculty, marking as "available" those members who could be released for service with the armed forces but listing as "essential" those who constitute the minimum staff necessary to conduct a sound teaching program.

Analysis of the medical school lists of "essential teachers" for the current academic year shows that, to July 1, 1942, 21 per cent of the physicians on medical school faculties were in Army or Navy service, as compared with 12 per cent of all physicians in the United States. In addition, the medical schools listed as "available" 25 per cent of the physicians of military age remaining on their staffs.

Some schools appear to have been overly zealous in releasing members of their faculties and to have retained insufficient staffs for the instruction of their students. The result can only be a sacrifice in the quality of the training of the medical students in these institutions.

Other schools have been more conservative and should be able to release additional physicians in 1943 toward meeting the quotas of medical officers needed for service with the armed forces.

Occasionally one hears the opinion expressed that medical teaching during the war might be done by practitioners who are over military age or are physically disqualified for military service. Such suggestions reveal a failure to realize that medical teaching has become very much of a specialty and that in many schools younger men not only carry most of the teaching load but are the most effective teachers. Before the war considerably more than half of the physicians teaching in medical schools were under 45, and on the average these men were devoting more time to teaching than were their older colleagues. Furthermore, most practitioners are too busy these days to assume much, if any, more teaching responsibilities. It is essential, therefore, that some of the effective younger teachers who are devoting all or a large part of their time to teaching be retained on the faculties of the medical schools. It is here that they can render their most valuable war service.

The lists of "essential teachers" as submitted by the medical schools are reviewed by the Medical Education Committee and the Allocations Committee of the Procurement and Assignment Service. The opinions of these committees in regard to the lists are then transmitted to the chairmen of the respective state committees of the Procurement and Assignment Service, who are responsible for making decisions as to availability or essentiality of the individual physicians in their states. Appeals from the decisions of state committees may be made by the dean of the school or by the physician concerned to the corps area committee or even to the Directing Board of the Procurement and Assignment Service. As already stated, the objective of this service is to retain adequate teaching staffs for the medical schools, but to do so without withholding from military service more than a minimum number of men who are physically qualified for such service.

MEDICAL STUDENTS

An adequate and uninterrupted supply of qualified medical students is obviously necessary if there is to be a continuing output of competent physicians from the medical schools. The procedures which have been followed up to the present time to enable medical and premedical students to continue their training are too familiar to need review. However, the lowering of the draft age to 18 years and the proposal of the Army and Navy to place selected medical and premedical students on active duty to continue their medical education have introduced new problems.

Dr. Edward C. Elliott and Brig. Gen. Joe N. Dalton have outlined the general plans for the proposed Army-Navy specialized training program. As citizens, taxpayers, parents and educators, we are interested in this entire program, but it is the medical aspects of it which concern us most deeply. The Directing Board of the Procurement and Assignment Service has questioned the advisability and the necessity of this program for medical students but, since it appears that they are to be included, there is nothing to be gained by further debating the point.

As the program is planned, some medical students will be on active duty in the Army and some in the Navy, and some, including the women and those who

are physically disqualified for military service, will continue as civilians on their own financial resources.

In order that there may be places for these students in medical schools after the Army-Navy specialized training program is operative, the Procurement and Assignment Service has recommended that 20 per cent of the places in medical school classes be reserved for students who are not included in the proposed Army-Navy programs. It has recommended also that, after the armed forces have secured their necessary replacements from the medical school graduates, the additional physically fit men in this group be commissioned and assigned to replace older men now in the service, who could then be released from active duty to return to the care of the civilian population.

It is from this group, together with the women and those physically disqualified for military service, that physicians to fill essential positions in civilian life, including war industries, will have to come. However, students who are not subject to military service and are paying for their own education are free agents to practice where they will. Possibly the creation of a War Manpower Commission Corps which would include these students and obligate them to accept assignments to practice where needed during the war would be worthy of consideration.

The plan provides that the medical course proper will be continued on an accelerated basis without change except for the addition of a few hours a week of military instruction.

The proposal concerning the premedical course is more disturbing. For a number of years, all but a small percentage of medical students have had three or four years of premedical training. Several months ago, the deans of medical colleges at their annual meeting voted to recommend that for the duration of the war all schools reduce their entrance requirements to two years of college work. The resolution embodying this recommendation stated, however, that "it is the judgment of the Association of American Medical Colleges that students cannot be prepared adequately to meet the modern requirements of medical education with less than this minimum preparation."

In spite of this, it is proposed that the premedical training under the Army specialized training program be limited to five terms of twelve weeks each. This is less than two college years. I sincerely hope that this will be adjusted to provide at least the two years of premedical education which is the minimum that has been required by the medical schools for almost half a century and is also the minimum required by many states for medical licensure. Even though the courses prerequisite for the study of medicine can be crowded into a shorter period, the students will be lacking in the intellectual maturity, the broader educational background and the judgment so important for this study.

A compensating element in this program is the fact that for a large proportion of students accepted by medical schools there will doubtless be an interval of three to six months between the time of their completion of the prescribed five terms of premedical work and their actual admission to medical school. It is probable that the students who have enlisted in the Army will be assigned during this interval for basic military training or for service in an Army general hospital. Either service will provide valuable experience as well as a desirable short respite from their studies before they embark on the accelerated medical course.

There are many details and questions concerning this program which have not yet been worked out, or to which the solutions are not yet available. In early December, when these training programs were first announced, there was still the important question as to how desirable and qualified premedical students could be kept in school instead of being inducted by the Selective Service System before the proposed specialized training program could be established. The Directing Board of the Procurement and Assignment Service recommended to the War Manpower Commission that Selective Service direct the deferment of premedical students in good standing until the proposed specialized training program becomes operative. This order was contained in Selective Service Bulletin 41 dated Dec. 14, 1942, which authorized deferment until June 1943 for premedical students who have had one or more years of college work. It has been recommended also that Selective Service provide for the deferment of any student accepted for admission to an approved medical school, provided such deferment does not exceed two years. On this recommendation national headquarters has as yet made no release.

In addition, the Adjutant General has ordered that premedical students who are inducted by Selective Service be assigned back to college to continue their training on an inactive status until the end of the term or semester.

On several occasions, the situation of premedical students and their selection for assignment to the proposed specialized training program was considered in joint conference by the Directing Board of the Procurement and Assignment Service with representatives of the Surgeon General of the Army, of the Surgeon General of the Navy and of the Selective Service System and, as a result of these conferences, the Directing Board of the Procurement and Assignment Service recommended that accredited medical, dental and veterinary medical schools give consideration to the early acceptance of qualified premedical, predental and preveterinary students for the classes of the calendar year 1944 as well as 1943.

This recommendation stated that students so accepted should be clearly qualified and desirable for training in these professional fields. After acceptance, students who are not in an Army or Navy reserve corps should be recommended for deferment to their Selective Service boards, and these recommendations carried to appeal boards if necessary. Such deferments should be only for the limited period until the proposed specialized training program becomes operative. Vacancies in these classes after the advance selections should be filled at a later date.

At a subsequent meeting, the following supplement was added to this recommendation:

That medical schools proceed with the selection of clearly qualified students for the classes of 1944, but that this be done with the definite understanding that these acceptances are tentative and subject to the approval of the Army or the Navy for those students who may be assigned for training in conformity with contracts which may be entered into between these services and the respective schools.

Students who are accepted for medical schools in accordance with these recommendations will be in a favorable position for deferment by Selective Service irrespective of their year in college. And indication by the medical schools that certain students are acceptable for admission will provide helpful information to the

Army and Navy boards which will be responsible for selecting students to continue their premedical training in the proposed specialized training program. In this manner, the medical schools will be rendering a valuable assistance in the selection of premedical students for the Army-Navy training programs and will have a voice in the selection of their classes for 1944.

Once the proposed Army-Navy specialized training program becomes operative, advance selections will no longer be necessary. In fact, final selection could then be well postponed until the last quarter or semester of the premedical program. The recommendation for advance selection of outstanding students is to safeguard the supply of qualified premedical students during this transition period.

INTERNS AND RESIDENTS

The Procurement and Assignment Service is concerned with hospital internships and residencies both because the internship is an important part of medical training and because certain resident physicians are essential for the clinical instruction of medical students and for the proper care of patients in certain hospitals. With hospital residents, as with the faculty of medical schools, the problem is to release as many as possible for service with the armed forces and still retain the minimum number essential for the proper functioning of the institution. Concerning interns and residents for 1943, the Directing Board of the Procurement and Assignment Service has issued the following statement:

Interns—Graduates of medical schools who hold commissions in the Army or Navy will be allowed twelve months' deferment of active duty for the completion of an internship. This makes it necessary that internships begin immediately on graduation. Medical school graduates who are deferred by Selective Service, under the Selective Service regulations, have their deferments continued through one year of internship. Medical school graduates who on account of sex, physical defects or other causes are not subject to induction or likely to be reclassified by Selective Service are not officially restricted as to the length of internships which they may serve but they too have a responsibility to make themselves available as early as possible for civilian services which contribute to the war effort.

Residents and Fellows—Interns who have already had a year of hospital service must be considered as residents for the duration of the war. Although the Army and Navy appreciate the importance of graduate training in the various specialties of medical practice, they do not feel that they can at the present time defer calling interns to active duty in order that they may continue specialized training in civilian hospitals. Therefore the only justification for the continuation of residencies and fellowships during the war is that they are essential for the provision of adequate medical care for the hospital patients or for the clinical training of medical students. In view of this situation, there are several principles that must be followed in the selection of hospital residents or clinical fellows for 1943.

First, the minimum number of residencies with which each hospital can function must be determined. For 1942 the Directing Board of the Procurement and Assignment Service stated that in general this number should be less than 50 per cent of the number of residents that these hospitals had before the war. For 1943 this number must be reduced still more.

Second, having determined the minimum number of residents that are essential, these should be selected from the following groups in order:

1. Physicians who for physical or other reasons cannot qualify for service with the Army or the Navy.

2. Present interns or residents who are deferred by Selective Service. Preference in this group should be given to those who have been deferred in class IV-F and class III-A or III-B and maintain a bona fide family relationship with wife and/or children.

3 Present interns who hold commissions in the Army or Navy. No requests for deferment of individuals in this group should be made until the possibilities of filling minimum essential residencies from individuals in groups 1 and 2 have been exhausted. It is impossible at the present time to give assurance that interns who hold commissions will be deferred. The Surgeon General of the Army and the Surgeon General of the Navy have assured the Procurement and Assignment Service of all possible cooperation in meeting this situation. On the other hand the urgent need for medical officers in this age group and the necessity of securing the authorization of the War and Navy departments to hold men with commissions in an inactive status beyond one year of internship make it imperative that hospitals make every possible effort to fill essential residencies and fellowships without depending on interns who hold commissions or those who might be subject to induction by Selective Service.

On January 28, in response to the joint request of the Procurement and Assignment Service and the Surgeon General of the Army, the Secretary of War sent the following memorandum to the chairman of the War Manpower Commission:

I agree with you as to the desirability of maintaining essential residencies in civilian hospitals, and securing consent to deferment for not to exceed an additional twelve months, of certain essential physicians who are already commissioned in the Army, subject to the following: (a) Each request for deferment will be handled as an individual case. (b) The residency for which the officer concerned is desired must be declared by the Procurement and Assignment Service for Physicians, Dentists and Veterinarians as being essential. (c) Each request for deferment will include a certificate from the authorities of the hospital concerned to the effect that effort has been made to obtain a physician who has not been obligated for the military service.

The Surgeon General of the Navy has authority to grant similar deferment of active duty to interns who hold commissions in the Navy.

In view of this authorization, superintendents of teaching and of large charity hospitals which are accredited for residency training may present to the chairman of their respective Procurement and Assignment Service state committees requests for the postponement of active duty for a limited number of interns or residents who hold commissions in accordance with the conditions stated.

Each such request will be considered as a special case by the Surgeon General. Action will be based on the certification by the hospital superintendent as to the essentiality of the position and the impossibility of filling it with a resident who does not hold a commission in the Army or Navy, and on the recommendations of the state and corps area chairmen and the central office of the Procurement and Assignment Service. No definite figure has been set for the number of such deferments, but it is essential that requests be limited to situations which are truly critical and which cannot be filled by physicians who have not been commissioned in the armed forces.

CONCLUSION

I want to assure you that the Directing Board of the Procurement and Assignment Service is deeply appreciative of the invaluable contribution that the medical schools of the country are making to the war effort and to pledge the cooperation of Procurement and Assignment Service to the medical schools in their efforts to maintain an effective program of medical education during the war.

MEDICINE AND THE WAR

COLONEL GEORGE F LULL

MEDICAL CORPS, UNITED STATES ARMY

A year has passed since the last meeting here in Chicago, and many changes have occurred. In December 1941 the personnel in the Medical Department of the Army consisted of 11,384 in the Medical Corps, 3,117 in the Dental Corps, 700 in the Veterinary Corps, 226 in the Sanitary Corps and 1,441 in the Medical Administrative Corps. Those were dark days. The Army was being built up rapidly, and the Medical Department was not keeping up. In fact, in May of last year we were under strength 7,000 Medical Corps officers.

Early in the spring it was realized that something had to be done in order to secure medical officers. Precedence was broken, recruiting boards were set up in each state and physicians were actually commissioned on the spot. Conditions started to improve in June, and when 1942 came to a close we had 35,594 medical officers on duty, only a little more than 3,000 under our total requirements. Dental and veterinary requirements had been met, the Sanitary Corps was still somewhat undermanned and the Medical Administrative Corps, although below strength, was being augmented at the rate of as high as 1,250 a month. At the present time about 900 Medical Administrative Corps officers are being commissioned from officer candidate schools each month.

The Army continues to grow, and an adequate medical service must be provided. This will take more medical officers, but due regard must be given to the home front and the civil population must receive adequate medical care.

The American soldier at present is receiving the highest type of medical care. Hospital commanders who visit the Office of the Surgeon General usually tell me what a fine staff they have and thank me for showing them the special favor of selecting men of such high type for their commands. When six or seven say the same thing in a few days, one realizes that the cross section of personnel supplied must be good, but of course, credit is taken for showing personal interest in the particular unit.

Since the last meeting many men have gone overseas, both toward the east and toward the west, and medical personnel in adequate numbers have accompanied all troops. Some of this personnel have gone to places where there has been great activity, and others have accompanied troops to places where there has been no action. Only a short time ago I received a letter from the wife of a medical officer in which she criticized the Surgeon General for the treatment shown her husband. She said that he had been sent to a small island in the Pacific where there had been no fighting to date, that it was a shame he had to stay there and take care of a lot of healthy soldiers and that he was losing his surgical technic. Should this island be attacked, however, a man who knows surgical technic will be sorely needed, and some one must be on hand to take care of the casualties as soon after they occur as possible.

Young medical officers entering the service object to being assigned to tactical units and think that anything they learn that is not purely medical is a sheer waste of

Read before the Thirty-Ninth Annual Congress on Medical Education and Licensure, Chicago, Feb. 15, 1943.
Released for publication by the War Department Manuscript Board, which assumes no responsibility other than censorship for the contents of this article.

time. The medical officer with a tactical unit is first, last and always a physician. He has to learn a little about a lot of strange subjects. He is first of all, the family physician to his unit. He must be expert in first aid and have a well rounded knowledge of sanitation and preventive medicine and know emergency surgery. In order to keep as many men on the firing line as possible he must exercise excellent judgment in the selection of patients for hospitalization. He must recognize infectious diseases early in order to prevent their spread. He is the most important link in the chain along which the wounded soldier travels.

A recent article written by an American physician with the British said relative to the qualifications of a medical officer in the forward area:

He should know the design and fitting to vehicles of water tanks, navigation by map and compass, how to light a primus stove in the wind, what to do if the lights fail in an operating tent, how to keep sick men warm in cool weather, what to do and say if the gasoline tank is filled with water, the technique to be adopted if when operating the enemy pays an unexpected visit, how to get out of a mine field into which you have unsuspectingly crept, etc.

The action in the present war is different from that in all previous wars in that it is more fluid, that is the movement is faster and changes take place with lightning rapidity. The writer quoted stated that the first knowledge of the enemy's presence may be the explosion of an antitank shell. The movement of dressing stations and other installations must be accomplished in a few minutes. In the last war the patient was taken back to the doctor, but now the doctor has to be taken to his patient. It is the patient who receives adequate early treatment who gets well. The man who gets back to a general hospital in the rear usually lives.

There have been developments since the last war which have saved hundreds of lives. Among these are the sulfonamide compounds, the utilization of blood plasma and tetanus toxoid immunization. Bullets and high explosive shells continue to kill and maim and although techniques of treatment change the fundamental principles remain the same. One of these principles I will repeat and that is to give the wounded man the proper treatment as soon as possible after he is wounded.

The proper employment of specialists is a question that comes up at any meeting and is probably of more interest to this group than to most. Not all medical specialists are being employed in their specialties. I know. However, a great deal of conscientious effort has been given to seeing that they are placed where the government will get the greatest good out of their services.

The secretary of one of the specialty boards recently wrote me that forty-two men in Army uniform appeared at the last examination. Each man was questioned about his duties, and all but two were working in the special field he was being examined in. Remember that one of the criteria in classification of specialists is certification by the board, and none of these men had been certified at the time of their assignment.

The Surgeon General welcomes information from the boards and from the colleges as to men who seem to be improperly cast in the present conflict. Be sure of your information, however, as sometimes we receive word which, on investigation, is not entirely correct. This fact was brought home to me recently when I ordered an officer's station changed at the suggestion of an outstanding American specialist. When the order was issued the specialist called me on the telephone and said that the officer had found out it was at his suggestion

and soundly berated him for his interference, saying that whoever had told about his being misused was not familiar with the true facts in the case. Fortunately, I was able to revoke the order by spending nearly an hour making long distance telephone calls.

Certain types of specialists are present in greater numbers in the Army than others. The percentages closely parallel those in civil life, as shown by a comparison with statistics of the American Medical Association. For this reason it is much easier to assign some specialists than others. The rosters received from various stations are constantly being checked to find qualified men as these men are needed for new units.

Since the last war the relative number of specialists has greatly increased and through the American boards and other agencies we are able to evaluate them. That is, if the officer is certified we take it for granted that he is qualified in his field. If he is not certified but is qualified, it is much more difficult to evaluate him.

There is another matter concerning which justifiable complaint has been heard and that is the formation of hospital units which have been kept on a training status for long periods and not used functionally. In a war of the present type this is bound to happen. Units are assembled for shipment to certain theaters and the tactical situation changes so that they are not sent. Priorities in the matter of shipping also have part in controlling this matter. The officers assigned to these units can be trained in a relatively short period while the training of the enlisted men takes much longer. We are now attempting to utilize in a professional capacity all medical officers of numbered hospital units at stations not too far distant from the unit's assembly point and leave only a small overhead with the unit to train and administer it. We feel that it is not proper to withdraw from civil life physicians whose services cannot be utilized except that we must have a reserve pool from which we can draw officers not only for original assignment but for loss replacements. The civilian physician cannot start to function as a medical officer the day he puts on a uniform. Though he is well qualified as a physician there are many things for him to learn of an administrative nature especially if he is to be the head of a service or section in a hospital or if he is to be assigned to a tactical unit.

In the first week of 1943 we changed the course at the Medical Field Service School from one month to six weeks. A new class enters every two weeks and continues until the course is completed. This means that three classes are conducted at the same time and the graduates are available for assignment every two weeks. It is highly advantageous to the individual as well as to the service for him to take this course as soon as he is commissioned. Unfortunately it will be impossible to send all newly commissioned officers as we have such a large backlog of officers already on duty who have not had the course.

There are at present fifteen courses in various professional subjects being given at civil institutions. These courses last for varying periods but most of them are of three or four months' duration. They are popular but many deserving officers have not been sent to them because they could not be spared from their present duties. They will be available for later courses. These courses are not intended to make specialists out of the officers but are in the nature of special instruction along lines which will improve the officer who already has some background for the particular type of work.

There is a demand for a certain number of women physicians for duty with the Women's Auxiliary Army Corps. Such physicians are hired as contract surgeons and sent to the WAAC training center at Fort Des Moines, Iowa. After a period of training they are given commissions in the WAAC. Apparently few women desire this type of work, as less than a dozen qualified physicians have applied although publicity has been widely distributed.

As medical educators you are no doubt interested in the status of the resident physician. At a recent meeting with the Procurement and Assignment Service it was estimated that next year there would be needed 2,800 residents in various institutions. This is a pronounced reduction from the present number. They will be chosen primarily from the following groups: (1) women physicians, (2) men physicians who are physically disqualified for military or naval service, (3) men physicians who do not hold commissions but are in class 3A, (4) alien physicians and (5) in limited numbers physicians who hold commissions but who may be deferred for an additional year before entering the service. The first four groups should be sufficient to furnish most of the needs.

Last month's data as to the status of residents were obtained by the American Medical Association from various hospitals. There were 648 replies received from 780 questionnaires with the following figures revealed: total residents 3,872, those with Army, Navy or Public Health commissions 273,¹ those who have applied for commissions 332, and those without military or naval status 3,267. Of these, 707 have been rejected physically and 472 are women. There remains available if physically qualified 2,088.

If we are to defer men who already have commissions, we will have to get some of the 2,088, and we have no claim to any of them.

Brig Gen Joseph N. Dalton spoke about the Army's specialized training program. Arrangements have been made to have a representative of the Surgeon General assigned to Col. Herman Beukema's office to handle the problems of premedical and medical education. This program, as far as we can see, will make some radical changes in premedical education but will interfere little with medical education as it is practiced at present. Every one hopes that the war will be brought to a successful termination before the program has had a chance to run for many years.

When you hear from a disgruntled officer please evaluate his statements before you form an opinion of the entire medical service of the Army. Remember that there are 35,000 physicians in the Army, all of whom are looking forward to one thing only, the successful termination of the war. Many are doing things they do not want to do but these things must be done. Also remember that there are a lot of medical officers satisfied with their temporary jobs, and most of these do not write to you.

In this brief statement I have touched on a few of the important problems facing us at this time. There are many more I have failed to mention. The solution to many of these problems has been and will be in your hands. You have been so willing to cooperate with us in the past that I feel the future is assured and we may be proud of American medicine's part in this gigantic struggle.

¹ A sample of one hundred of those who claim army commissions shows only forty three actually commissioned.

OBSERVATIONS ON THE PREVENTION AND MANAGEMENT OF PEPTIC ULCER

RUSSELL S. BOLES, M.D.

PHILADELPHIA

When one approaches the problem of peptic ulcer one is confronted with a bewildering mass of data concerning its pathogenesis, diagnosis and treatment. Since preventive and effective treatment depends on a knowledge of the cause of ulcer, it is of interest to consider at once the factors apparently involved in its incidence and its production.

INCIDENCE IN MILITARY AND CIVILIAN POPULATIONS

From many quarters today come reports of the increasing incidence of peptic ulcer since the beginning of the war.¹ This is true in European countries as well as in America, especially in the military forces. Whether ulcer is actually affecting an increasing number of persons or whether it is being recognized in persons not previously suspected of having it will depend on a critical analysis of the situation after the war is over. It has been suggested that the large scale physical examination of draftees has brought to light an unsuspected prevalence of ulcer and that most of the men in the Army found to have ulcer had it before admission. In Germany an increase in the incidence of peptic ulcer is said to have been progressive since the World War, the increase is attributed in part to improved methods of diagnosis and especially the more extensive use of x-ray examinations. In many instances it has been obvious that ulcer symptoms appearing after admission to military service have been due to activation of old ulcers from the added stress and strain of army life. In this connection, however, there is scarcely a single factor mentioned as a possible cause of ulcer or ulcer aggravation that cannot be refuted by contradictory findings. For instance in the British army¹ overexertion and army rations are emphasized, while in the British navy² the rations and the steady diminution of active manual work as a result of the increasing number of mechanized and motorized units is held at fault. In many reports lack of proper nourishment is stressed while in others ravenous overeating after heavy exercise is considered responsible. In the civilian population attention may have been drawn more frequently to the presence of ulcer because people at large have been rendered stomach conscious by increasingly high pressure salesmanship via press and radio for all kinds of remedies, diet fads, alkalization and vitamin essentials.

Both in the military and civilian populations, duodenal ulcer has shown an apparently greater increase

Read before the Section on Practice of Medicine at the Ninety Third Annual Session of the American Medical Association Atlantic City, N. J. June 10, 1942.

than gastric ulcer and as might be suspected, chiefly in males. In connection with these observations it is of the utmost importance to determine exactly on what basis they are made. Certainly the diagnosis of ulcer cannot be made on the history alone, though this is most important, and indirect x-ray evidence is not reliable. Therefore it is required that the diagnosis should not be made unless positive x-ray evidence of the ulcer accompanies a positive history or proof of the lesion is secured at operation or autopsy. If one would accept only positive x-ray evidence secured under the most favorable conditions and only by skilled observers, duodenal ulcer would not appear to be on the increase in the civilian population, judging from the experience of E. P. Pendergrass. He reports in a personal communication that in 1940 1,000 cases of stomach and duodenum were studied in the University of Pennsylvania Hospital. In this series 19 cases of gastric ulcer were found and 94 cases of duodenal ulcer. In 1941 1,343 cases were studied in which 27 cases of gastric ulcer were found and 92 cases of duodenal ulcer. Actually, in these studies there was no change in the number of cases of gastric ulcer but there were 24 per cent less cases of duodenal ulcer. The statistics of the first world war show that gastric ulcer was diagnosed in the United States forces almost three times more frequently than duodenal ulcer, at the present time in civilian and military groups approximately the same ratio, but exactly reversed, is being reported. Definite reasons for this should be available and I believe will be when this subject is more critically investigated. One of the reasons for instance, for the present figures may be that duodenal ulcer makes itself more often clinically manifest than gastric ulcer. This is suggested by Madelung,³ who showed in a study of 10,000 autopsies that, in 17.8 per cent of cases, ulcers or scars of ulcers were found, of these 70 per cent were in the stomach and only 30 per cent in the duodenum.

A number of factors having a common influence in the military and the civilian population have been mentioned as predisposing causes of the increase in ulcer. Among these is the part played by anxiety, grief and worry over loved ones, which is of course, equal in military and civilian groups. Another is the disruption of the usual routine of life, which has been reported as much in civilians by defense industries and activities as among the soldiers by military activities. Irregularity and haste in eating, rather than the quality of food, are properly condemned, especially in the urban groups who, incidentally are affected more by ulcer than those in the country. Seasonal peaks in ulcer incidence have been attributed to lower vitamin intake and increased respiratory tract infections.⁴ Not long ago Alsted,⁵ in a thorough study of the increase in ulcer in Denmark, concluded that no one factor could be held responsible as in all probability the constant and continuous changes in social and living conditions are all involved. According to Alsted, the incidence of dyspepsia has increased with the increased tempo of life. He comments somewhat sadly that, in spite of advances in the social sciences, there is less security today than in the past. He believes the definite improvement in dietetics has

been largely offset by the adoption of all kinds of fads and that our primitive instinct for selection of food has been lost and we are at the mercy of the sometimes brilliant but occasionally erratic and misleading conclusions of the human mind.

After all is said and done, it must be admitted that only time and a carefully balanced analysis of all the facts will provide the true story concerning ulcer in the armed forces. There would seem to be nothing unusual in the fact that a young man, probably of sedentary habits, who is suddenly transferred from civilian to military life, with the change of diet and habits that the latter requires, develops a type of dyspepsia that may simulate ulcer. Furthermore, much depends on the roentgenologist and the medical officer making the diagnosis of ulcer. The heightened interest of certain examiners and the impatient indifference of others when dealing with "dyspepsia" require on the part of those responsible great stability of judgment in evaluating the data on this subject. The number and variety of factors that can constitute a considerable source of error in diagnosis is so great that at the present time it would be well to withhold any convictions in the matter.

INCREASE IN CONSUMPTION OF TOBACCO

Perhaps the one factor in both military and civilian groups that is most consistently mentioned in association with ulcer especially since the beginning of the war, is the increased incidence of smoking. Major Crampton⁶ of the United States Army has recently emphasized that cigaret consumption was more than doubled in the United States during the first world war years 1916-1919, rising from 25 billion to 53 billion annually. The increase in consumption of tobacco in the Army in that period was nearly three times as great as in the general population, the result as he says of the increased tension of camp life and war consciousness. Crampton informs us that cigaret smoking has enormously increased since the last war, the consumption now being eight times as great as in 1916, and that there was a 12 per cent increase in cigaret consumption in the four months ended in April 1941 as compared with the corresponding months of 1940. The probable significance of this may be appreciated when one realizes that in 1930, as reported by Bastedo, 123 billion cigarettes were manufactured, i. e. 1,500 a year for every American man, woman and child over 14 years of age. Emphasis is given to these exceedingly important observations on cigaret smoking because of the increasing suspicion of the relationship it bears to ulcer.

Ulcer develops notoriously more frequently in a certain type of individual—an autonomically unstable, excitable, energetic individual—one who appears to possess an ulcer diathesis, as it is called by virtue either of heredity or of environment but chiefly the former. It is true that different individuals may react differently to tobacco, and even different parts of the same individual may react differently than other parts. It is generally recognized, however, that "nicotine primarily and energetically affects the autonomic nervous system" and all candidates for ulcer have a susceptible autonomic nervous system.

Tobacco, furthermore, is admitted to affect the circulation especially the vasomotor tone of the arteries,

veins and capillaries. It is probable that through such a mechanism Mosinger and Bonifaci⁸ produced both acute and chronic round ulcer in guinea pigs by the injection of nicotine. Recent investigations have demonstrated anew the importance of disturbances of the circulation, especially those of a functional nature, in the pathogenesis of ulcer.⁹ Tobacco is recognized as a cause of hyperacidity. Rosenblum¹⁰ has shown that cigaret smoking in the fasting state produces a significant increase in the free and total acidity of the gastric juice as well as a considerable increase in the volume of the juice in patients with duodenal ulcer. Schnedorf and Ivy,¹¹ as a result of their investigations, cautioned persons with ulcer against the undesirable effects of straining their tolerance to tobacco, their findings indicating that smoking might aid in producing ulcer or in aggravating existing ulcer. The effect of tobacco on secretion in conjunction with its effect on the vascular system, justly places it under suspicion as a factor in the cause and chronicity of ulcer. In the German army the authorities are so convinced of the etiologic importance of smoking that efforts to regulate the habit have been made, punitive measures under some circumstances being enforced. An exhaustive treatise by Lickint⁷ on the effect of tobacco on the human body has recently been published.

INFLUENCE OF CIRCULATORY CONDITIONS

Reference has been made to the influence of circulatory conditions as a cause of ulcer. No attempt will be made to discuss this theory of ulcer production in detail. The idea is not new. Virchow, of course was the first to involve the vascular system in the cause of ulcer. He believed that ulcer resulted from thrombosis and embolism in the smaller gastric vessels. Since then a number of writers have maintained that disturbances of the blood supply to the stomach were of primary importance in the etiology of ulcer. Recent investigations demonstrate that an abnormal blood supply, especially the result of recurrent or persistent vasomotor spasm, may lead to impoverishment of the mucosa with ischemia, erosion and eventual ulceration. The work of Nedzel,¹² Berg,¹³ Riggs and her collaborators,¹⁴ Griffith and myself⁹ supports such a contention which is based particularly on the peculiar vascular characteristics of the vascular bed of the stomach and its rich vasomotor innervation, both of which predispose it to local deficiencies in blood supply. Some writers have mentioned the possibility of a disturbance of gastric nerve supply in the etiology of ulcer, a hypothesis postulated many years ago by Grote,¹⁵ who believed that the actual pathologic factor was not the increased secretion of acid so much as an increased sensibility of the gastric

nerves. The observations of Nothhaas¹⁶ in respect to this are interesting, in that not all the vasoneurotic suffer from ulcer, but all ulcer patients exhibit the typical capillary change of vasoneurosis, the latter being attributed to a constitutional deficiency of the vascular system.

CORROSIVE ACTION OF ACID

As a result of recent physiologic investigations the conclusion is reached that the corrosive action of the acid gastric juice and the proteolytic effect of pepsin are the major factors in the cause and persistence of ulcer.¹⁷ That an impasse seems to have been reached concerning the role of acid is suggested by the fact that the acid corrosion theory of ulcer production is probably the oldest of all theories, and it should be obvious by now that the problem of pathogenesis is destined to make little further progress in this respect. It is encouraging, therefore, that thought is being given to the cause of the hypersecretion itself, especially whether it may be of central origin and dependent on neurogenic and psychogenic influences. Meyer and others¹⁸ make the highly interesting comment with regard to acidity and ulcer "that hyperacidity in cases of duodenal ulcer is preceded by hypoauidity, and that hyperacidity may be caused by an unknown factor or by the ulcer, and not vice versa, as is generally believed." In Thompson's "Practical Medicine" published in 1903 it is stated that hyperacidity is the rule in ulcer and it is believed it may be caused by the ulcer.¹

Nothing seems to afford more promise of throwing light on this aspect of ulcer than the study of the influence of the midbrain. Recognition must be given to the position which psychosomatic medicine is assuming today, and in peptic ulcer, particularly, analysis along this line would appear to be reasonable and fruitful.¹⁹ Intimation of the importance of the midbrain in the life cycle of ulcer is afforded by the pathologic studies of Boles and Riggs,²⁰ in which ulcer was shown to be associated with and presumably due to lesions of this structure.

In view of all the intriguing experimental study given to the pathogenesis of ulcer, especially by such brilliant students of the subject as Ivy, Mann and Dragstedt, it would be without reason to deny that acid plays an important part, but that it plays the primary and major role reflects an attitude that bears questioning. Adherence to such a doctrine explains, I believe, why the medical treatment of ulcer until a few years ago had not materially changed in twenty or more years and why the surgeons in the same period have completely reversed themselves concerning its surgical management. It was only a few years ago that Balfour,²¹

truly a great surgeon made the statement that "there is no operation more useful than gastroenterostomy in cases of duodenal ulcer, except in carefully selected cases. The operation in suitable cases can be depended on to give excellent and permanent results in more than 90 per cent of cases." In 1926 Moynihan, another brilliant surgeon expressed the opinion that no operation in surgery had produced more striking or swifter results than gastroenterostomy. Today it is quite a different matter—only the carefully selected case is considered suitable for gastroenterostomy, and partial gastrectomy which but a short time ago was violently opposed by the American surgeon, is being accepted with growing enthusiasm. In a recent editorial in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION—Wangensteen is reported as emphasizing that the most important criterion of an acceptable operation, speaking of duodenal ulcer, is that it reduce gastric acidity effectually, and that he feels that the three quarter resection meets these demands. The editorial goes on to say that the only known manner in which the secretion of acid may be diminished effectually is by sacrificing a liberal portion of the gastric mucosa. In the case of gastric ulcer, Walters is reported as saying that proper surgical treatment has been followed by excellent results and in his experience, recurrence has not taken place when one-half the stomach has been removed. The operative risk of resection, according to the editorial should not exceed 5 per cent, and in the hands of skilled surgeons should be less than that. While one greatly hesitates to question the opinion of the leading surgeons of today in this matter it is but natural to compare their enthusiasm and conviction to that of equally capable surgeons of but a few years ago, who held directly opposite opinions, notwithstanding that in the meantime the objective they both sought namely, a reduction in gastric acidity, is still shrouded in almost as much mystery as it was in the earlier days. Let it not be forgotten, furthermore, that peptic ulcer occurs in persons with a low acid secretion—that they heal in the presence of normal and increased degrees of acidity—and that they do not develop in many persons with decided hypersecretion.

MEDICAL AND SURGICAL TREATMENT

That the patient is fortunately getting the break in this startling reversal of opinion is a matter of comfort as the better surgical minds agree that the uncomplicated duodenal ulcer is better left to the inventions of the internist. Even he in many cases, as well as the surgeon, is still doggedly determined to treat hyperacidity rather than ulcer, but despite this I am sure that all of us will agree that the use of any one of twenty-four substances so far recommended for gastric acidity, or the injunctions to go off on a hunting trip or the granting of a suppressed desire has less potentiality for harm than the actual removal of three fourths of one's stomach.

Allen²³ states in a recent article that "duodenal ulcer is primarily a medical problem and that approximately 80 per cent of patients with this lesion respond to conservative measures." In the Lahey Clinic²⁴ only 8 per cent of 3,285 duodenal ulcers were submitted to

surgery, whereas 23 per cent of 249 gastric ulcers were operated on. More gastric ulcers come to operation because of the greater hazard of cancer. In the Mayo Clinic²⁵ 60 per cent of gastric ulcers are treated surgically, obviously because of the fact that malignancy of such ulcers was found in 8 to 10 per cent of cases. Partial gastrectomy is the operation of choice because the chance of malignancy is greater than the chance of postoperative fatality, the chance of the former being approximately 10 per cent, while that of the latter was 39 per cent in 1940. In the case of gastric ulcer decision to operate should depend somewhat on the location of the lesion. The Mayo Clinic reports that malignancy was found in 10 per cent of lesser curvature ulcers while 65 per cent of the prepyloric ulcers and all of the greater curvature ulcers were malignant. In older persons, the larger the ulcer, even on the lesser curvature the greater the chance of malignancy. Great caution is necessary in any decision concerning malignancy because, as Eusterman has said, malignant gastric ulcer may successfully mimic a benign lesion, and Sara Jordan²⁶ advises us that "neither the size of the ulcer nor the age of the patient nor the presence of normal acid or hyperchlorhydria should lessen our suspicion of carcinoma."

To me it has always been remarkable, in this matter of differential diagnosis between a benign and a malignant gastric lesion how much dependence is placed on objective findings, particularly x-ray findings, and how little on the clinical subjective symptoms, which are infinitely less likely to lead one astray. In my experience a suspected or demonstrable lesion of the stomach in a middle aged or elderly person, with persistent anorexia, a low or absent acidity, a mild or increasing anemia and failing weight and strength is invariably malignant regardless of the x-ray interpretations. On the other hand a good appetite, a normal or increased acidity, a normal or especially a high hemoglobin and red cell count indicate that the lesion is benign. Of the subjective symptoms the one I have found that least often fails in differential diagnosis is the state of the appetite, a good appetite, though the patient may be afraid to eat, because of eventual discomfort, means a benign lesion. Persistent anorexia means malignancy, other things being suggestive.

IMPORTANT FACTORS IN PRODUCTION OF ULCER

The prevention and management of peptic ulcer, in view of the bewildering mass of data I have touched on and to which I have but briefly referred would appear to be a despairing assignment were it not for the fact that certain ideas persistently emerge from the maze of theories surrounding the problem. I shall enumerate those that I believe are of importance in explaining the development of ulcer and on which effective treatment must be based.

1 Only a certain type of individual will produce an ulcer. It is a type with a suggestive physiologic, psychologic and anatomic pattern. It is probable that the pattern is fashioned by a certain qualitative type of autonomic nervous system.²⁷ As a rule, these indi-

viduals have energetic effective personalities and they live in a constant state of excitement, anxiety, fear or some other emotional ferment. In some, with little external evidence of instability, outward calm may hide inner chaos.

2 The peculiar quality of the autonomic nervous system referred to is susceptible to influences that favor ulcer production. These influences bring about alterations in the blood supply to the stomach and duodenum that diminish the vitality of the mucosa of these structures. Secondly, the affected mucosa becomes subject to the corrosive action of acid gastric juice. Acid and pepsin are essential factors in the development of ulcer, but the mechanism of their production is imperfectly understood, certainly any attempt that is made to control their secretion should take into consideration the part played by the midbrain and various systemic disturbances.

3 Tobacco in an ulcer susceptible individual appears to be a consistent factor in the cause of ulcer and is of major influence in the prevention of healing and in the recurrence of the lesion.

4 Respiratory tract infections, such as chronic infections as are found in the gallbladder and appendix, and gastritis apparently predispose to ulcer.

5 As far as eating habits are concerned a greater risk of ulcer comes from hurried and intemperate eating rather than from the quality of the food eaten. Long intervals between meals and eating when fatigued, worried or angry are almost certain to invite ulcer. One would be surprised what can be eaten when in a happy frame of mind.¹

6 Anaphylaxis in certain individuals may explain ulcer production.

TREATMENT

In the prevention and medical management of ulcer, it is obvious that all persons but especially the ulcer susceptible type, should avoid as far as possible the influences I have mentioned. Such persons should be advised to forego such destructive emotional extravagances as fear, anxiety, anger and ordinary perverseness. They should feel free to eat what agrees with them but avoid eating it when fatigued or in a bad state of mind. Generally speaking, alcohol and other irritants to the stomach should be used, if at all, in great moderation. They should restrict their use of tobacco to not more than six cigarettes daily and should not smoke these on an empty stomach. They should rest after eating when possible and not subject their nervous system to the effects of too great application of the mind and too little manual activity.

I believe the complications of perforation and hemorrhage are largely preventable. They usually occur in persons who will not observe the general precautions I have outlined—who have overloaded their stomachs or have subjected themselves to unusual physical effort—or who have experienced some unusually severe psychic or emotional trauma. Justification for the latter statement is afforded by the important observations of Stewart and Winsor²⁸ in England. They noted a statistically significant increase of perforated ulcers in the first two months of heavy air raids (September and October 1940) over the entire period for 1937-1940. The large majority (93 per cent) occurred in men and mostly between 50 and 60 years of age. The

same authors noted a considerable increase in deaths from peptic ulcer, the increase in the second year of the war being 28 per cent for men and 22 per cent for women.

Considering the precautions that must be observed to prevent a healed ulcer from breaking down it would seem highly inadvisable for the military authorities to accept any one for military service who has ever had a history of proved peptic ulcer or massive hemorrhage or to keep in military service any one in whom a peptic ulcer has been demonstrated by an experienced roentgenologist or at operation. If such individuals must be kept in service, provision for small frequent feedings should be made.

If an ulcer is so active that it is seriously interfering with the work and comfort of an individual, bed rest for two to three weeks is desirable. The diet must be adjusted to the circumstances, in any case being of a bland, palatable nature and taken in not less than six feedings daily in moderate quantities. In no case should it be too greatly restricted in variety or for too long a time. Psychologic as well as physical reasons dictate the necessity for this. The diet should be devised for the patient and not for the ulcer. Specifically a lack of vitamin C and protein content has been noted in ulcer cases and in balancing the diet adequate provision should be made for these essentials.¹⁴

Of medicines, but few are required. Appropriate doses of bromides, phenobarbital, belladonna and one of the colloidal aluminum substances or the various alkaline antacids usually are all that are temporarily necessary to control pylorospasm and hyperacidity. In some cases nocturnal secretion must be controlled by means of an all night drip of milk or neutralizing solution. In other cases it is sufficient to awaken the patient once or twice during the night by means of an alarm clock to take some nourishment or an antacid. Sufficient evidence especially of an experimental nature has accumulated to justify consideration of urogastone²⁹ and enterogastrone³⁰ in the treatment of ulcer, as they do depress secretion and inhibit motility. Needless to say these are but the general principles of a medical regimen and modification of them would be necessary to suit individual cases.

Finally are the indications for surgery and the operation itself. The generally accepted indications for surgery are perforation, recurrent hemorrhages, especially in persons past middle life, obstruction that is not relieved within a short time by a medical regimen, inability to relieve acute symptoms and, in the case of gastric ulcer, any suspicion that malignancy may be present. In other words, complications, intractability or a suspicion of malignancy should afford the only grounds for operation.

Failure to relieve symptoms usually connotes an intractable ulcer. Before one advises operation, however, for a so-called intractable ulcer, it should be thoroughly understood that it is the ulcer and not the patient that is intractable. Poor results will follow in the latter case as surely as in the former. Intractability of a patient is not going to be corrected by any surgical operation yet devised to my knowledge, and, if persuasion or anything else can correct it, it were better to try it before rather than after operation. Lowering mortality records is all very good, but serious consideration must likewise

²⁹ Gray J. S. Present Status of Urogastone. *Am J Digest Dis* 8: 365 (Oct.) 1941.

²⁸ Stewart D. N. and Winsor D. M. Incidence of Perforated Peptic Ulcer. *Lancet* 1: 259 (Feb. 28) 1942.

be given to the future welfare of the patient. So in advising surgery, the temperament of the individual must come in for as exacting consideration as his physical status. "Jitterbugs" are poor subjects for surgery. As the general practitioner frequently has the deciding voice concerning operation, he should inform himself of "the trends of good surgical experience" and of the prospects of a "cure" for his patient and he should know that a "cure" is based in large measure on the temperament and the cooperation of the patient as well as on the judgment and ability of the surgeon. Both the physician and the surgeon should make a more serious effort to prevent complications. I believe such efforts carry more promise of success than does the surgical treatment for the complication.

As for the type of operation it is being accepted that conservative surgical procedure, such as gastroenterostomy and pyloroplasty, are no longer justified as routine operations for gastric or duodenal ulcer.¹ While the arguments for wide resections are reasonably sound—and the mortality rate in the hands of the best surgeons is intuitively low—and the immediate prospects for the patient relatively good—the annoying thought obtrudes itself that eventually nature will compensate for the loss of three fourths of the stomach by enabling the remaining fourth to take up the function of the removed portion and who knows but the curse of acidity for which the operation was done, will be upon us again! In fact just that has already occurred. The surgeon who is unfortunate enough to have a patient develop a jejunal ulcer following subtotal resection of his stomach may never see or hear from that patient again. His follow-up statistics, therefore, to carry significance, should take into consideration all "absentees." That jejunal ulcers are going to occur after partial gastrectomy as they did after gastroenterostomy, though perhaps not so often, depending on how much of the stomach is removed, is a matter I believe more and longer follow-up studies will reveal. Within two weeks I have encountered 2 cases of jejunal ulcer, 1 having perforated, following partial gastrectomy for duodenal ulcer. Lahey³¹ reports he has had seven proved postoperative jejunal ulcers in a series of 137 consecutive subtotal gastrectomies. I would plead therefore for a more critical comprehensive analysis over a long term period of all ulcer cases with especial consideration given to the variations that occur in the life cycle of ulcer, whether it is medically or surgically treated, before too positive opinions are expressed in favor of one or the other.

SUMMARY

To summarize this question of surgery, then, I would recommend that operation only be considered in selected, complicated cases of ulcer. With growing enlightenment on the pathogenesis of ulcer it might be well to reconsider the virtues of conservative surgery.

While at the present time there would seem to be no satisfactory alternative to radical surgery, in complicated cases let it be done with the definite understanding that elimination of acidity is not the last word in the treatment of ulcer, and that patients with ulcer, as surely as those with diabetes, tuberculosis or pernicious anemia, are candidates for future trouble unless physicians and surgeons remember that the disease may be arrested but not cured!

Rittenhouse Plaza

ABSTRACT OF DISCUSSION

DR SARA M. JORDAN, Boston. Among the many important points which Dr. Boles stresses none is more important than the question of when the ulcer is to be medically treated and when it is to be surgically treated. This involves a consideration of the etiology of the ulcer. Dr. Boles has in recent years shown us some data on the effect of the midbrain on alterations of circulation in the stomach, which to my mind are synchronous with the spasm which occurs in the stomach and which, when talking about acid, one has in the back of one's mind as part of the picture. It is a question not only of treating acid but of treating spasm. When we say we treat acid and treat spasm, we really mean we are treating the ulcer by combating acid and by combating spasm. Dr. Boles warns us that perhaps we are sometimes talking about intractable ulcer when we really mean an intractable patient. That is true but I think he will agree that when a patient has been intractable long enough the ulcer often becomes intractable. This is especially true when the ulcer is located on the posterior wall of the duodenum or the posterior wall of the stomach, and the penetration of the ulcer involves the pancreas, with the resultant pain. Dr. Boles's admonition is useful when surgical resection of the stomach looks so easy in skilled hands and when the results are so good and when the risk is so low. The surgeon may often be easily induced by the internist who has become weary of trying to manage the patient to perform the operation when perhaps it is not really necessary. The person who is emotionally tense and often the one who is well controlled externally is the one who needs the best psychiatric guidance when he has an ulcer diathesis. One of the things we must remember in dealing with gastric ulcer is to be sure that the ulcer has fulfilled all the criteria which are so well established for the permanent healing of ulcer, namely the disappearance of the x-ray defect of symptoms and of occult blood, and, in the judging of the disappearance of the x-ray defect, the complete assurance that there is absolutely nothing left of that x-ray defect not even the slightest bit of induration in the stomach wall. It is believed now that any gastric ulcer which recurs should be regarded as at the present or in the future, a malignant lesion. We have in our department a group of patients whom we saw perhaps ten years ago, with hyperchlorhydria and with pyloric spasm and evidences of duodenal change and whom we have been successful in keeping under our care and who have not developed ulcer. In another small group, in which we were not able to control the diet and habits, an ulcer has developed. I think it is not out of the realm of possibility to try to prevent ulcer.

DR FRANK H. LAHEY, Boston. I feel strongly about this question of prevention. There is not any doubt in my mind that if one could frighten people before they are faced with a catastrophe and get them to adjust their habits—smoking, eating, drinking and working habits—so that they would devote the same serious attention to their alteration at that stage as they will after they have had two or three hemorrhages, then I think probably one could do a great deal as relates to the prophylaxis of ulcer. Apparently it is a human attribute not to accept an ulcer as really serious until there have been two or three hemorrhages that threaten fatality or the patient has had pyloric obstruction or perforation. No one today, I think, can defend primary surgery in the treatment of ulcer. All our ulcer patients come to us only as medical failures. They represent the intractable posterior wall ulcers. We in surgery see many anterior wall ulcers in the course of cholecystectomies and other operations represented then only as scars but they are the interperitoneal ulcers that in this anterior position can fold themselves in. The posterior wall ulcers are of course, mechanically the same problem as the calloused, chronic varicose ulcer above the ankle—it is fibrosed, it has lymph stasis, it has venous stasis, it lacks oxygen and it is mechanically unable to fold itself in—and so that type of ulcer is our major problem. I wish it were possible to improve our figures in gastric cancer; they are so bad, so many patients come so late. There is certainly one thing that I would like to preach as a result of experience and that is that it is the duty of the medical men and the gastroenterologist to follow carefully and to accept the responsibility for following those patients with low gastric acids and any question of a lesion by x-rays. It is in the patient with low

³¹ Lahey, F. H. Indication for Gastric Resection. *Am. J. Digest. Dis.* 8:180 (May) 1941.

gastric acids that one should be sure that he does not place the responsibility for return check-up examinations on the patient but that the doctors take it. It is this group with low gastric acids and anacidity who have lesions that are debatable. We agree that we have never seen a benign ulcerating lesion on the greater curvature, we agree about the dangers of prepyloric lesions. But there are certain patients with prepyloric spasms who require exploratory operation to be certain that they do not have cancer. In some of these cases the simulation of a malignant condition is so great that one cannot safely say, even with a gastroscope, that it is not malignant. Gastroenterostomy should not be routinely applied, because it leads to high incidence of gastroduodenal ulcer. It is equally bad for every patient to have a subtotal gastrectomy. I would infinitely rather do a somewhat unsatisfactory operation on a bad risk patient such as gastroenterostomy and have him alive and have him take his risk of 16 per cent of gastroduodenal ulcer than submit him to an undue risk of subtotal gastrectomy.

DR HYMAN I GOLDSTEIN, Camden N. J. Dr Boles mentioned the great increase in cigaret smoking since the first world war. Millions of women, some of whom now also serve with our army and navy, smoke a great many cigaresses, and I wonder if gastric disturbances, including gastroduodenal ulcer, will increase among women during this present crisis. May I ask the author how he would correct or attempt to cure the "ulcer diathesis" which he finds so important a factor in ulcer etiology. Ancient writers knew of the relation of disturbances of the brain and mind to the occurrence and aggravation of gastritis and ulcer of the stomach—Diocles (fourth century B. C.), Galen (130-200 A. D.), Fabricius Hildanus (1560-1634), Rhodius (1587-1659), Jean Fernel (1497-1558), Jean Riolan (1539-1605), Joannes Heurnius (van Heurne 1543-1601), Capivaccius (died 1589) and others. Galen (On Prognostics chapter XI) recites how he treated Emperor Marcus Aurelius (121-180 A. D.) for his aggravated stomach trouble and "indigestion" after his battles. Galen also quotes Diocles (fourth century B. C.) under "De Melancholia" (in *De Locis Affectis* Paris 1513, book III, chapter VI), giving a complete and accurate description of ulcer symptomatology and its relation to mental disturbances. As to modern medical management of ulcer, it is no different than in the time of Celsus (35 B. C.-27 A. D.). Celsus gave a special soft smooth diet without acid or acrid substances, and light wine to be not too hot or too cold. Paul of Aegina (625-690 A. D.), Sexapion (ninth century), Jean Fernel (1497-1558), J. Varandæus (died 1617), Joannes Scultetus (1595-1645) and others treated ulcer of the stomach, as we do today, with terra sigillata (kaolin or aluminum silicate) and other preparations to protect the erosions and ulcerations. Paul, thirteen hundred years ago (book III, section 37) discussed "Affections of the Stomach," as did Macellus Empiricus (379-460? A. D.), Oribasius (325-403 A. D.), and Aëtius Amidenus (502-575 A. D.) before him, and he gave terra sigillata (aluminum silicate), Samian earth, Lemnian earth and milk and starch to protect the eroded and ulcerated gastric mucous membrane. Scultetus (1622) says this treatment stimulates the healing of ulcer of the stomach by protecting it, just like wax put on an inflamed foot. Time does not permit more than mention of the names of Rhazes (860-932), Hally Abbas (930?-994), Avicenna (980-1036), Albucasis (1013-1106), Avenzoar (1070-1161), Averrhoës (1126-1198) and Franciscus de Piedmont (1265?-1319) in this connection.

DR. RUSSELL S. BOLES, Philadelphia. I did not state that the preoperative study is vitally important, and no doubt Dr. Lahey, being the competent surgeon that he is, would acknowledge that his successes are somewhat due to the competent preoperative study that his patients get under Dr. Jordan and in the gastroenterologic clinic. I agree with Dr. Jordan on the different measures of combating acidity except for pyloric gastric resection. I think that is an unjustifiably radical step for combating acidity. As far as the congenitally intractable patient is concerned, I can't conceive of any operation helping him. He is going to continue to be intractable and therefore to continue having trouble, no matter what kind of operation he has. Dr. Lahey drew attention to cases with adhesions to the pancreas, which explain some of the intractable ulcers. I agree that there should be no question in any of our minds that we

do have to resort to radical measures for the correction of such complications. Dr. Jordan questioned some of the symptoms that I emphasized in my paper, and I want again to emphasize that in my experience they are symptoms of early malignancy. We are not usually in doubt about the symptoms of late, well established, lesions but I still maintain that a persistently poor appetite is not necessarily a symptom of late cancer. Dr. Jordan raised the question of operating for recurrent gastric ulcers and mentioned that they are the ones that, in a certain percentage of cases in her experience, are going to be malignant. I should like to ask her in turn why, if such ulcers are malignant, do they heal? I don't understand how a malignant ulcer is going to heal and then recur again and maybe again and again. The medical failures are pretty desperate cases that have to be met with and I am in sympathy with them, but I cannot altogether feel that a gastric resection is all we can do. When that is all that is left for Dr. Lahey, that is one thing, but I disapprove of the tendency of many other surgeons to do radical operations when there are plenty of both preventive and medical measures left. I found the slides presented by Dr. Goldstein interesting. He asked how we are going to relieve the ulcer diathesis. I don't think we have any better way of doing that than he has. All we can do for those patients is to relieve the factors that we know do seem to precipitate ulcer. He mentioned children and asked why children get ulcers when they are under no strain. There are lots of children who are under strain, with their problem parents and many other things. I could give plenty of reasons why some children get ulcers.

MOTILITY OF THE HUMAN COLON

THE NORMAL PATTERN, DYSKINESIA AND THE EFFECT OF DRUGS

A. J. ATKINSON, M.D.

H. F. ADLER, Ph.D.

AND

A. C. IVY, Ph.D., M.D.

CHICAGO

"Constipation," diarrhea, distention and colic are common complaints which may result from temporary or prolonged alterations of the normal pattern of the colon. Yet there seems to be a paucity of knowledge regarding the motor activity of the human colon and much divergence of opinion regarding its response to stimulating and "antispasmodic" drugs.

Alvarez,¹ in summarizing our knowledge, says "The colon is a sluggish organ with few and slow movements. The movements of the haustra are very slow. A few times a day there are 'mass movements' which carry material usually from the transverse colon over into the sigmoid region. Much of the progress of material in it seems to be due to the pressure exerted by new material coming down from above."

The concept that material from above exerts a sort of "plunger" effect on material below is due primarily to the inadequacy of the x-ray method for studying colonic motility. The x-ray method provides an outline of the colon and yields precise information regarding rapid movements in the colon such as occur in "mass movements" and defecation. The method rarely reveals those movements which are responsible for transporting material for short distances, and it does not reveal in a qualitative and quantitative manner the correlation or

Dr. Peter Rosi aided the authors in securing subjects. From the Department of Physiology and Pharmacology, Northwestern University Medical School.

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1942.

1. Alvarez, W. C. An Introduction to Gastro-Enterology. New York: Paul B. Hoeber, Inc., 1940.

lack of correlation between the different types of motility present simultaneously in adjacent segments of the colon. This explains why Todd,² regardless of his extensive studies, "could not see how material moved forward from the cecum to the ascending colon." Because his observations were so extensive, he did observe contractions which at times affected one segment after another in the transverse colon. We shall emphasize later the importance of the segmental activity observed by Todd.

The variable effect of drugs on the human colon is enigmatic unless one knows that different types of motility exist in different segments and that the type of motility conditions the response. It will be seen that some drugs affect propulsive motility, others affect tone and nonpropulsive motility, and others appear to act by improving the coordination between segments.

METHODS

The introduction of the tandem balloon method³ for the study of motility has revealed that (a) the activity in different segments varies, (b) to obtain propulsion of contents the activity of adjacent segments must be coordinated, (c) to comprehend a complete picture of the motility repeated continuous records of several hours' duration must be made and (d) two or more segments must be studied simultaneously. Also with the tandem balloon method it is possible to determine when the motor activity of one segment is propagated to an adjacent segment.

To measure the propulsive force of a contraction we constructed special apparatus.⁴ The use of this apparatus and the passage of contents from a colostomy yield direct evidence of propulsive activity.

Preliminary experiments were performed on trained, unanesthetized dogs.⁴ The results guided our experiments on the human colon. Four human subjects with colostomies were studied mornings and afternoons for eight months. The rectum and lower sigmoid of each had been removed six to eighteen months previously and the subjects were in excellent condition. Patients were studied an hour after breakfast when the colon and sigmoid were empty and again after a standard luncheon. We started with a three balloon system which was discontinued, because occasionally after drugs which stimulated propulsion the balloons were tied into a knot, rendering their removal hazardous. We then used one or two balloons. Our results on human beings pertain only to the descending colon, from the splenic flexure downward to the colostomy.

RESULTS

Control Studies—In order to obtain quantitative and qualitative control studies of the motility of the human subjects continuous records were made during seventy periods of at least one hundred and fifty minutes each. Additional control periods were interspaced during the drug experiments. Control records of from twenty to thirty minutes were obtained before the drugs were administered. Under usual conditions contents were not discharged from the colostomy. Unless these patients had diarrhea they expelled no further contents after the early morning enema.

Amount of Motility—Control records revealed that there are periods of quiescence and activity in the human⁵ and canine³ colon. The activity of the segments varies, but at times all segments are quiet. About 50 per cent of the time there is motor activity, of which only 10 per cent is propulsive, the remaining activity is local, segmental and nonpropulsive with varying degrees of tone.⁶

Coordination of Segments—After many records were observed it became evident that adjacent segments had to manifest coordination before a propulsive wave in one segment could "pass" to an adjacent segment. Sometimes a propulsive wave would start in one segment, and the type of motility in the adjacent segment would be modified. Then the propulsive wave would appear in the adjacent segment. At other times a propulsive wave would start and the motility of the distal segment would not be modified. This indicated either that the propulsive wave was very local or that the distal segment was not integrated so as to receive the propulsive wave.

Colonic Dyskinesia—These facts suggested that stasis could occur if a segment could not "receive" a propulsive wave. Furthermore, when a strong propulsive wave occurred in one segment and the distal segment was manifesting nonpropulsive activity on considerable tone, the subject felt tension or a cramplike pain. The subjects frequently complained of cramps when a strong propulsive wave occurred in the proximal segment and failed to pass to the distal segment. A cramp did not occur if the propulsive wave passed to the distal segment and contents were expelled. In cases of diarrhea, liquid contents could pass through a hypertonic segment.

These observations suggest that some propulsive waves are confined normally to a segment of about 5 cm in length. Other propulsive waves travel from one segment to a more distal segment and cause definite propulsion of contents. If the distal segment manifests rapid, rhythmic, nonpropulsive activity on considerable tone, it usually does not accept a propulsive wave. X-ray examination would detect this condition only by accident or, if the fluoroscope should be used for from ten to twenty minutes. "Constipation" could be the only symptom. However, if the distal segment manifests rapid, rhythmic, nonpropulsive activity on considerable tone, and then a relatively vigorous propulsive wave occurs in the cephalad segment, symptoms of distress may occur. However, the incompatibility of the wave type is not so common a cause of tension and pain as is the relative intensity of the propulsive wave in the cephalad segment and the degree of tone of the distal adjacent segment.

We use the expression colonic dyskinesia to indicate that ill motion between adjacent or successive segments of the colon which functionally produces sufficient obstruction to the propulsion of contents to produce stasis and symptoms of tension and pain. Or, as Alvarez might say, colonic dyskinesia represents a type of disturbance of the normal gradient of the colon. We believe the ill motion is due to an extrinsic or intrinsic disturbance of coordination. It is obvious that a saline cathartic by liquefying the contents might provide temporary relief but would have no effect on the underlying condition, it might aggravate the condition.

STIMULATING DRUGS

We have previously reported in detail our observations on the effect of certain drugs which stimulate the propulsive activity of the human colon.⁶ For completeness it is appropriate to review the more important observations.

Fig. 1—Complete cessation of motility in the human descending colon for ninety minutes after the subcutaneous injection of 0.7 mg of atropine sulfate.

Solution of posterior pituitary (2 units intramuscularly) increased the propulsive motility of the colon in all our subjects. The response occurred after a latent period of a few minutes and occasionally lasted as long as twenty minutes. Prostigmine methylsulfate (0.25 to 0.50 mg intramuscularly) increased both the propulsive and the nonpropulsive activity. The response occurred usually in twenty minutes and lasted one to two hours. This response was most striking. Ergotamine tartrate (0.25 mg intramuscularly) had no definite effect, 0.35 mg intravenously in our dogs caused increased propulsion and defecation occasionally. It was found, however, that 0.25 mg of ergotamine would potentiate the action of prostigmine in human beings. Because of these observations, it was believed that a combination of solution of posterior pituitary, prostigmine methylsulfate and ergotamine tartrate would produce a prompt and sustained increase in motility. Accordingly, solution of posterior pituitary (1.25 units), prostigmine methylsulfate (0.25 mg) and ergotamine tartrate (0.25 mg) were injected at the same time intramuscularly. Propulsive motility occurred promptly in response to the solution of posterior pituitary and the tone and propulsive motility of the colon were augmented for six to eight hours. Contents were expelled throughout the entire day, indicating that the propulsive motility of the small intestine had also increased. The pulse and blood pressure tested at intervals were not changed and the patients did not complain of side reactions at any time.

"ANTISPASMODICS"

Opium, belladonna and their derivatives have been used for years as so-called antispasmodics. More recently "spasmalgin," "benzedrine," "octin," "syn-

tropan" and "trasentin" have been introduced. We have studied the effect of all these drugs on the human colon, some more intensively than others.

Morphine Sulfate—Much evidence⁷ has proved that morphine has no motility-inhibiting action on the human colon. We used morphine sulfate to induce hypertonus of the dog's colon as a method for the assay of various alleged antispasmodics.

The hypodermic injection of 8 mg of morphine sulfate increases the nonpropulsive motility and tone of the human colon (i.e., the part we studied). The hypertonus may persist without any evidence of propulsive motility for several hours depending on the dose. In 3 instances our subjects reported with diarrhea. After collecting the discharge for a period 8 mg of morphine sulfate was administered. The discharge ceased with the disappearance of propulsive waves. Similar effects have been observed in a patient with an ileostomy.⁷ Morphine obviously tends to constipate because it decreases or abolishes propulsive activity. It may relieve the pain in colon colic by central action, and possibly by altering motility from a propulsive to a nonpropulsive type.

The use of the multiple balloon technique reveals why some investigators have reported that morphine relaxes the colon. In our studies a decrease in tone in the presence of rapid, rhythmic waves occurred in one of the segments under observation in nine out of thirty-three tests. In other segments the tone was increased.

No so-called antispasmodic that we have used dramatically inhibits the hypertonus induced by morphine.

Fig. 2—Complete cessation of motility of the canine colon for eighty minutes after 20 mg of trasentin intravenously.

unless given intravenously (dog) in relatively large doses. If morphine hypertonus is similar to the hypertonus and spasm which occur in diseases of the colon, it is not surprising that physicians are searching for a uniformly potent antispasmodic.

Atropine Sulfate—Atropine sulfate was administered to our human subjects in doses (0.75 to 0.8 mg) just sufficient to cause some dryness of the mouth. Smaller doses have no definite effect. In 5 instances the spontaneous motility was completely abolished for one to two hours (fig 1). In three tests, the amplitude of

* Total motility time in percentage that the colon is active per 30 minute period of experimental time.

† Propulsive motility expressed in percentage of total motility.

the contractions was diminished and the periods of quiescence were increased. In two the nonpropulsive motility was unaffected but propulsive motility did not occur. These effects were of course, analyzed by comparison with control motility records.

It has been shown that atropine has some antagonistic effect on the increase in tone and nonpropulsive motility induced by morphine in the dog's colon. Only six experiments of this nature were done on our human subjects because morphine must be given with caution, and the results were identical with those obtained on the dog. A combination of atropine sulfate (0.7 mg) and morphine sulfate (8 mg) was injected intramuscularly. Propulsive motility was abolished for two hours and tone and nonpropulsive motility were partially antagonized. This is shown in the accompanying table.

The combination of papaverine hydrochloride $\frac{1}{3}$ gram (0.02 Gm), pantopon $\frac{1}{2}$ grain (0.01 Gm) and sulfuric acid ester of atropine $\frac{1}{60}$ grain (0.006 Gm) has been referred to as "spasmalgia." We used it because these drugs are supposed to have antispasmodic action. The aforementioned dose was given orally to our subjects. From forty to sixty minutes later the tone and nonpropulsive motility were increased, and propulsive motility disappeared in nine of twelve experiments for a period of seventy minutes. The action of "spasmalgia" has been reported previously in similar experiments.⁸

We have not studied the effect of papaverine and pantopon separately on the human colon. Bargen and Jackman,⁹ using the single balloon technique, report that pantopon acts much like morphine and that papaverine hydrochloride usually but not always causes a decrease in tone.

⁸ Pantopon is a preparation containing the hydrochlorides of the alkaloids of opium, principally morphine.

⁹ Bargen, J. A. and Jackman, R. J. The Influence of Papaverine on Muscular Tone of the Intestinal Tract. Surg., Gynec. & Obst. 68: 749 (April) 1939.

Amphetamine Sulfate ("benzedrine")—Amphetamine sulfate has been used in the management of colonic distress as an antispasmodic,¹⁰ supposedly to stimulate sympathetic nerve endings and thereby inhibit the colon. We gave 10 mg orally or intramuscularly and did not give larger doses that might disturb sleep. The pulse rate of all subjects was increased.

The effect on colonic motility was not definite. In all of twenty-two experiments the quantity of both propulsive and nonpropulsive motility was not altered. In eight of the twenty-two experiments there seemed to be some depression of the tone and amplitude of the contraction, in seven the coordination of the motility between segments, compared to control records, appeared to be improved, but not decisively, in the remaining seven no effect was discernible. No definite quantitative effect was recorded.

In other studies in which we have administered the same amount of amphetamine sulfate some subjects have reported a "call to stool" when central stimulation by the drug became definite. This might be due to the central effects of the drug, though it is possible that the qualitative improvement in the coordination between segments facilitated passage of contents to the rectum.

Diphenylacetyl-Diethylaminoethanol Hydrochloride ("Trasentin")—This synthetic alkaloid with an atropine-like action was studied intensively. When given intravenously to the dog it counteracted morphine-induced hypertonus better than any drug we have used to date except atropine. This is compatible with the theory that it acts directly on smooth muscle.

Canine Experiments—In fifteen experiments 10 to 50 mg of the drug was given intravenously to our trained dogs with colostomy. The propulsive and nonpropulsive spontaneous motility were depressed or abolished for as long as eighty minutes (fig 2). The records of the tandem balloons showed that the distal

Fig 3—Periodicity and improvement in coordination of segments of the colon in the dog after 50 mg of trasentin intramuscularly.

colon usually is depressed longer than the proximal colon. Atropine sulfate has a similar differential action.¹¹

⁸ Pantopon is a preparation containing the hydrochlorides of the alkaloids of opium principally morphine.

⁹ Bargen, J. A. and Jackman, R. J. The Influence of Papaverine on Muscular Tone of the Intestinal Tract. *Surg Gynec & Obst* 68:749 (April) 1939.

In nine experiments hypertonus of the colon was induced by intramuscular administration of 16 mg of morphine sulfate. Intravenous injection of 25 mg of "trasentin" immediately depressed motility and tonus for a period of about twenty minutes. The intravenous injection of "trasentin" was usually not toxic to the dog. It was slightly toxic when given with morphine sulfate, as was indicated by salivation, apprehension and an increase in pulse rate. Unfortunately when as much as 200 mg of "trasentin" was administered intramuscularly (twenty experiments) it had no effect on the hypertonus induced by morphine.

The effect of 50 to 200 mg of "trasentin" intramuscularly on the spontaneous motility of the colon was then studied in twenty experiments. The total motility of the colon was decreased approximately 15 per cent, which is less than that usually resulting after 1 mg of atropine sulfate. However, the doses of "trasentin" used had a very definite effect on the quality of motility. The periods of activity of the various segments became more uniform and the coordination between different segments was definitely improved. The propagation of a wave of activity from one segment to the next now occurred in sequence (fig 3) more frequently than under normal conditions. In this connection, Spier, Neuwelt and Necheles¹² observed that "trasentin" only partially depressed the motility of the alimentary tract and in so doing seemed to restore the normal gradient.

Human Experiments In the 4 human subjects thirty-three experiments were performed in which 50 to 75 mg of "trasentin" was given intramuscularly or 75 to 225 mg orally. The route of administration in the dosages used made no significant difference in the results. In ten of the tests a 35 per cent decrease in total motility occurred (fig 4) in fifteen, or 14 per cent, and in the remainder with the smaller doses no decrease occurred. In every test but five the quality of motility was definitely influenced. The motility became more periodic, the periods of activity being separated by periods of quiescence. As in the canine tests, the coordination between segments was improved.

In 3 instances the drug was given orally when the patients reported with diarrhea and cramps. The balloons were inserted, a control record was made and the drug administered. One patient received 75 mg, the motility became more regular and the cramps were relieved. The same response occurred in the 2 other patients who had been given 225 mg, this dose, however caused a gradual decrease in the tone of the colon in both subjects (fig 5).

Fig 4—Complete cessation of motility of the human colon after 150 mg of trasentin orally

It was observed that after an oral dose of 225 mg the subject sometimes complained of a burning sensation in the epigastrium. In 2 instances, morphine sulfate was given four hours after "trasentin" (225 mg). The patients became apprehensive, their pulse rate increased, and they complained of slight malaise. This

we interpreted as being due to "morphine-trasentin" incompatibility,¹³ mentioned in the case of the dog. For this reason we could not determine in man the effect of "trasentin" on the hypertonus of the colon induced by morphine. We believe it is important to remember that morphine sulfate and "trasentin" should not be used in close sequence clinically.

Fig 5—Reduction in the quantity of motility and tone and a return toward periodicity in a segment of the descending portion of the human colon after 225 mg of trasentin orally. In the upper tracing the tone is high and the movements relatively rapid a type of motility that is not conducive to propulsion when present in two adjacent segments.

Methyloctenylamine Hydrochloride ("Octin")—This drug was administered to our 4 human subjects in the doses shown in the table. The drug did not alter the normal control pattern of motility in our subjects within two hours. In 1 instance after being given 2 tablets (300 mg) the patient reported increased propulsion of colon contents.

Synthopan—This drug was administered intramuscularly in doses of 10 or 20 mg in ten experiments. No effect was discernible in our records (table). This was not anticipated because the drug has a spasmolytic action on the isolated rabbit's intestine. However, this drug has peculiar pharmacologic properties. It has an oxytocic action on the intact uterus of the guinea pig, rat and dog.

COMMENT

Our observations show that it is important to consider the quality as well as the quantity of motility in the study of the human colon. It is important, we believe, to distinguish between the two functional types, namely the propulsive and the nonpropulsive motility. The knowledge that different types of motility may occur in adjacent segments of the colon and that the type of motility in adjacent segments influences the extent of travel of a propulsive wave aids in the comprehension of colonic dyskinesia and its consequences. It seems to be apparent from our records that the existence of a normal gradient in the colon depends on the existence of coordination between the various functional segments of the colon. The more intimate nature of the coordinating mechanism is uncertain.

Atropine sulfate and "trasentin" were clearly the best depressants of spontaneous colonic motility among the drugs studied. In the doses used atropine sulfate (0.8 mg intramuscularly) produced a more decided

12 Spier Ernst Neuwelt Frank and Necheles Heinrich Clinical Study of a New Synthetic Spasmolytic Drug Diphenylacetyl Diethyl aminoethanol. Am J Digest Dis 6 387 (Aug) 1939

13 Van Duzen R E Slaughter Donald and Winter I C The Effect of Trasentin and Morphine on the Urinary Bladder of the Unanesthetized Dog J Urol 44 667 (Nov) 1940

depression than did "trasentin" (75 mg intramuscularly). Although "trasentin" did not abolish motility as a rule, it did improve the coordination between segments and established a gradient or type of motor pattern conducive to propulsion. Atropine sulfate may be found to have the same action if graded doses are employed. But it should be noted that the larger doses of atropine sulfate depress both propulsive and non-propulsive motility.

Our results on the effect of atropine sulfate and "trasentin" in therapeutic doses on the hypertonus of the dog's colon induced by morphine provide an explanation of why these drugs are not uniformly successful in the management of colonic colic. If the hypertonus in the colon or one of its functional segments is too great, these drugs in ordinary therapeutic doses, which do not give rise to objectionable side effects, will have little or no effect. Ideally we need a drug which specifically antagonizes the hypertonic segments without altering the normal segments. This may be asking for the impossible. At least we should like to have a drug which in nontoxic doses counteracts morphine induced hypertonus to a greater extent than atropine sulfate and "trasentin" do.

Our results demonstrate that before it is claimed that a drug depresses colonic motility in man the drug should be studied on patients with a colostomy, using preferably a two balloon system. At least such a study should be conducted on the trained colostomized dog, since the results on isolated segments of intestine are apparently unreliable. It also is our belief that a drug should be assayed several times on the same and different subjects, the effect of one or two administrations may lead to erroneous interpretations. However, drugs which do not paralyze the intestine may be useful clinically. Such drugs may affect the mechanism, causing the dyskinesia without significantly affecting normal mechanisms.

SUMMARY

The normal pattern of the motility of the human colon has been studied in a series of 4 men with a colostomy by repeated experiments over a relatively long period. We have attempted to explain how an alteration of the normal pattern, by influences which affect the coordination between segments, may produce "constipation" and symptoms of tension and colic. The effect of various drugs on the propulsive and non-propulsive motility was studied. Simultaneous injection of solution of posterior pituitary (1.25 units), prostigmine methylsulfate (0.25 mg) and ergotamine tartrate (0.25 mg) was found to cause a prompt and prolonged increase in the propulsive motility of the human colon without side reactions. Morphine sulfate (8 to 16 mg) is not an antispasmodic in the sense that all motility is inhibited. It increases the tone and non-propulsive motility and definitely decreases or abolishes the propulsive motility. Of the various "antispasmodic" drugs studied, atropine sulfate and "trasentin" proved to be the most potent depressants. Atropine sulfate (0.7 to 0.8 mg intramuscularly) may abolish all spontaneous motility of the colon for a brief period, whereas "trasentin" (50 to 75 mg intramuscularly) is less likely to do so. "Trasentin" may depress nonintegrated motility in such a manner that propulsion is favored and a normal gradient established. The effect of these drugs is more striking on the distal than on the proximal colon of the dog. The ideal "spasmolytic" drug for the colon has yet to be discovered.

303 East Chicago Avenue

ABSTRACT OF DISCUSSION

DR WALTER C. ALVAREZ, Rochester, Minn. When these studies were published, I wrote Dr. Atkinson to tell him how valuable I thought they were. It seemed to me that they threw light on the problem of the patient who says that his distress is due to the fact that gas does not move onward. I have long suspected that in these cases the contractions are localized and are not propulsive and wavelike. A man can swallow a lot of air and pass it through the bowel without any distress, while the gas which forms after the eating of some food to which he is allergic seems to stay in one place and will cause pain for an hour or more. I was interested in the authors' discovery that in different persons there are different patterns of colonic activity with different ratios of the comfortable wavelike contractions to the uncomfortable, nonprogressive contractions. I suspect that persons with a sensitive bowel and a tendency to mucous colics have more of the nonprogressive contractions. Years ago I found that any poison, such as nicotine or anoxemia, which injures the synaptic nervous mechanism in the intestine wipes out the propulsive type of wave and leaves what I call a systolic type of contraction of many parts of the intestine at one time. It seemed to me that the systolic type of contraction might well cause pain. I am pleased to see that in a pharmacologic study some attention is now being paid to the influence of drugs on the two types of waves. I have always felt that our knowledge of the pharmacology of the intestine would never advance until research workers noted particularly the action of drugs in producing the propulsive type of contraction.

DR J. P. QUIGLEY, Cleveland. The report by Dr. Atkinson and his associates represents a serious, painstaking investigation of three intestinal problems: (1) the fundamental physiologic motility of the colon, (2) the deviations from the normal which occur in dyskinesia and so forth, and (3) the action of drugs on this normal and abnormal motility. The pharmacologic results can be generally accepted as reported. They constitute a valuable contribution, and the value will be augmented if subsequent investigations demonstrate that the abnormal colon responds in a manner similar to the normal. Certainly there is reason to anticipate that the combination of solution of posterior pituitary, physostigmine and ergotamine found so effective in augmenting colonic propulsion should be effective in relieving the distressing distention from intestinal gas which plagues the individual who ascends to a high altitude. The proposed interpretation of the results is so important that one might wish that the differentiation between propulsive and nonpropulsive motility was made by a direct method involving the measurement of the rate at which something was transported through each portion of the colon. Especially adapted types of roentgen or multiple bolus studies may be suggested. Accurate determinations of the pressure gradients at adjacent segments of the bowel would also be desirable. To attempt this differentiation by any indirect method such as balloon studies is less satisfactory, since it involves many loopholes.

DR JAMES W. WILTSIE, Binghamton, N. Y. I wish to show two slides illustrating mass movement in the colon. The roentgenograms in this case were taken by a small portable machine of 15 milliamperes power. The exposure time was eight seconds. I discovered, incidentally, that short time exposures produced the effect of actual motion. Several patterns of transport movement are found to occur in the colon. Originally this case was one of fecal impaction in the cecum and ascending colon. Seven irrigations were required to clear the colon of this impaction. The first slide is that of a barium sulfate enema introduced immediately after the seventh irrigation. The exposure was made two or three minutes after introduction of the enema. Within this brief period the barium sulfate had reached the cecum and was being returned. The cecum is fixed by adhesions. The left half of the transverse colon shows a double shadow, the central denser portion indicating the diameter of this segment at the beginning of the eight second exposure, the lighter outer portion the diameter at the end of the exposure. The streaked appearance of the shadow in the right half of the transverse colon indicates barium in motion. My interpretation of this film is that active dilatation in the left half of the transverse colon is sucking the enema from the proximal por-

tion of the colon as the initial phase of a definite transport movement caudad. Since statements have frequently appeared in the literature to the effect that it is impossible to pass a colon tube beyond the rectosigmoid juncture I wish to show several slides (of different patients) in refutation of this erroneous belief. Slide 3 shows beyond the possibility of successful contradiction that the tube has been passed as far as the hepatic flexure. Slide 4 shows the tip of the tube in the upper portion of the ascending colon. Slide 5 was taken after the tube had been in place at least fifteen minutes and indicates an attempt of the colon to expel it as indicated by the large pelvic loop recession of the tube from the midtransverse colon to the splenic flexure and by a loop coiled in the rectum representing the expelled portion.

DR. A. J. ATKINSON, Chicago. Atropine and trasermin were clearly the best depressants of spontaneous colonic motility among the drugs studied. Intramuscular injection of $1\frac{1}{4}$ units of solution of posterior pituitary with 0.25 mg. of prostigmine and 0.25 mg. of ergotamine produced a prompt and sustained increase in motility without any undesirable side effects. I have used this combination of drugs successfully in cases presenting megacolon and other conditions of colonic stasis. The work reported is not just another drug study on the human colon; it is an attempt to correlate in a practical manner the knowledge that has been gained in the laboratory with various clinical problems.

PLATED OSTEOPERIOSTEAL GRAFT

EARL D. McBRIDE, M.D.

Assistant Professor of Orthopedic Surgery, Oklahoma University School of Medicine, OKLAHOMA CITY

The osteogenic virtues of the osteoperiosteal graft are unquestioned. This type of graft has been of secondary importance chiefly because it lacks the stabilizing rigidity of the cortical graft. Also, there is less confidence in the thinner graft for fear that it will not provide a preponderance of osteogenic material.

Fig. 1—Preparation of the host bed. The periosteum is incised and elevated sufficiently for the cortex to be flattened uniformly to the size of the graft. Intervening fibrous tissue and callus are not excised or disturbed except as absolutely necessary to restore alignment.

However, it has been found that if the osteoperiosteal graft is compressed firmly to a freshened bed on the ununited fragments, resulting osteogenesis compares favorably with that of a full thickness graft, and the simpler surgical procedure permits its application in situations in which the more extensive bone sawing excisions would be contraindicated.

Phemister and Harkins¹ and Delangeniere and Lewin² have described the advantages of the osteoperiosteal graft as a procedure in which they used ligatures and muscle pressure for fixation. The remarkable advances in the use of metallic fixation since the introduction of vitallium and especially hardened steel

together with the use of the sulfonamide compounds, have brought about many liberties in bone surgery not heretofore considered prudent or feasible. These two agents used with the osteoperiosteal graft make possible

Fig. 2—Excision of graft. Removal of osteoperiosteal graft $\frac{1}{8}$ inch thick from the crest of the tibia by retracting the muscles from the lateral margin of the tibia and starting the chisel or bone saw transversely $\frac{1}{8}$ inch below the crest. The graft is first outlined on the anterior surface of the tibia but is cut laterally from the crest rather than being chiseled out lengthwise as is usually done. This is to prevent curling up of the graft and to insure uniform thickness.

the treatment of nonunion in instances in which the typical cortical graft could not be considered.

When the osteoperiosteal graft is squarely covered by a smooth flat vitallium plate and gently but firmly squeezed to its bed on the bone fragments by the usual screw fixation, neither absorption nor necrosis occurs as one might think. On the contrary, such overlying support is a protection from erosive influences, and the firm contact of the graft to its host bed provides the necessary basis for plastic coalescence, just as compression by sponge pressure stabilizes the skin graft to create coherence. Such compactness of covered pressure and sealing-in effect lessens the exposure of the graft substance to attack by the processes of absorption and promotes the permeation of budding vessels and proliferating osteogenic cells.

INDICATIONS

1 *Use in the Presence of Chronically Infected Tissue*—When chronically infected tissue is present the use of such a method, together with the sulfonamide compounds, offers possibilities of using the bone graft in cases in which a more extensive operation of cortical graft would meet disaster.

Fig. 3—Plating of graft on fragments. Application of the metal plate directly on top of the graft in the customary method. The graft can be tied to the plate by catgut previous to application, since there is a tendency for the graft to slip about under the plate while the drill holes are being made.

2 *Delayed Union*—In cases of delayed union the more simple procedure of a plated osteoperiosteal graft is justified at an earlier date than one would resort to

Read before the Section on Orthopedic Surgery at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1942.

1. Phemister D. B. and Harkins H. N. Simplified Technique—Onlay Graft for Old Ununited Fractures in Acceptable Conditions. J. A. M. A. 109:501-506 (Nov. 6) 1937. Phemister D. B. Split Grafts in the Treatment of Delayed and Nonunion of Fractures. Surg. Gynec. & Obst. 52:376-381 (Feb. 2A) 1931.

2. Delangeniere Henri and Lewin Philip. A General Method of Repairing Loss of Bony Substance and of Reconstructing Bones by Osteoperiosteal Grafts Taken from the Tibia. Surg. Gynec. & Obst. 30:441-447 (May) 1920.

with the greater traumatism of a full thickness graft. Thus, instead of waiting and splinting over a period of months, during which adjacent joints become stiffened and tissues atrophied, an osteoperiosteal graft can be plated onto the fragments and passive motion begun in a few weeks with full confidence in the security of the fragments.

3 Use as Shding Graft in Tibia—In nonunion of the tibia the graft more often may be taken from the upper or lower fragment of the same leg, since atrophy or weakness in the graft material is not so great a factor with the use of the metal plate for internal fixation.

4 Nonunion with Loss of Substance—In most cases in which there is considerable loss of bone substance one of the classic bone graft methods should be used

Fig 4 (case 12 in table) —Before and after application of plated osteoperiosteal graft. This was a severely mutilated hand with persistent sinuses still poorly healed at the time of operation. There was considerable loss of substance. A bone graft made it possible to obtain movement in the ankylosed wrist.

However, the plated osteoperiosteal graft has proved very efficient in a number of instances in which the intervening fibrous space was not more than 1 inch.

TECHNIC

The anesthetic should be general. In compound fractures preoperative preparation should include attention to chronic scars, sinuses or ulcerations. Hot fomentations, local application of antiseptics and elevation of the part in bed may be necessary for several days prior to the operation. The incision for exposure of the ununited fragments should avoid scar tissue or healed sinuses as widely as possible. The graft is best taken from the tibia. In a previously infected field, when the graft is taken from one of the fragments of the tibia, there should be two carefully separated incisions. The graft should be taken first to prevent contamination

or the instrumentation should be divided, one for each field. The graft is cut very thin and accurately with a saw and a thin osteotome. The graft should be slightly larger than the plate in length and width.

Fig 5 (case 12 in table) —Three months after operation showing consolidation of the ununited fracture.

Fig 6 —Photomicrographic section cut crosswise of osteoperiosteal graft and its bed after removal of the vitallium plate from its surface. Area A is the layer of fibrous tissue originally the periosteum of the graft. Area B is the bone tissue of the host bed. Note the microscopic spear of ingrowth into the fibrous structure. New vessels have formed a cytogenetic relation between the new tissue introduced and the bone tissue in the neighborhood.

The manner of taking the graft is important in that the graft should be cut in uniform thickness. Instead of chipping it endwise with a chisel placed on the flat sur-

face of the tibia, it is preferable to retract the muscles from the lateral margin of the tibia and start the chisel or bone saw about $\frac{1}{16}$ inch below the crest. By being cut transversely at this depth, parallel with the anterior surface of the tibia, the graft remains flat and does not curl up. Previous to cutting the bone laterally, one should make an outline of the size of the graft on the anterior surface with the osteotome, driving it $\frac{1}{16}$ inch in depth (fig. 2).

PREPARATION OF HOST BED

The extent of readjustment of the fragments depends entirely on the nature of the malunion or deformity. The periosteum of the fragments should be carefully elevated and conserved. If at all possible, the intervening fibrous tissue and callus should not be excised or

an inflammatory reaction is likely to occur, the wound is dusted and all raw surfaces are rubbed with a half and half mixture of powdered sulfathiazole and sulfanilamide.

The retracted periosteum of the host fragments is brought as evenly as possible up over the slightly extended edges of the graft and even over the plate as much as possible in order to seal in and protect the graft. Plaster immobilization is applied. In four to six weeks regeneration of bone, in addition to the sustaining adequacy of the metal plate, affords passive and active motions in uncomplicated cases. The plate need not be removed after union, unless indicated because of irritation.

This method has been used in a series of 17 cases, 15 of which are analyzed in the accompanying table.

Plated Osteoperiosteal Bone Grafts Analysis of Cases

Fractures	Age	Duration from Date of Fracture	Date Grafted	Condition of Local Field	Passive Motion Begun	Mobility and Function	Complications	Plate Removed	End Result
1 J. C. R* compound comminuted left tibia and fibula middle 3d	49	10 mos	10/25/40	Healed sinus in 3 mos 1 bone loss	8 wks	6 mos	None	No	Good union

disturbed. Local trauma should be as mild as possible, especially when chronically infected scar tissue prevails (fig. 1). Burrows³ and others have shown that resection or freshening of the bone ends in bone grafting is not necessary. With the periosteum retracted the surface of the cortex of both fragments is evenly flattened as a receptive bed for the graft. The graft is then spanned across the fibrous gap between the fragments and smoothly fitted to its bed. In the tibia, the graft is plated preferably to the lateral aspect of the bone. Good muscle covering should be sought in other bones. The metal plate should be of a solid rectangular form and of smooth surface. It is clamped directly on top of the graft, fixing it with screws in the conventional manner to compress evenly and gently the underlying transplant to its bed (fig. 3). In compound fractures when

Union was obtained in all cases. Osteogenesis as followed by x-ray examination, compared favorably in rapidity and quality with that which might have been expected with a full thickness graft. The intermediary tissue between the ununited fragments ossified with favorable rapidity, and it seemed unnecessary to remove it as is commonly practiced.

In case 6 the plate was removed at four months because of slough, but the graft remained uniformly adherent, and firm union of the fragments was obtained. In cases 1 and 5 there was $\frac{3}{4}$ inch to 1 inch loss of bone substance. The intervening fibrous tissue was not removed but osteogenesis developed throughout the gap, with progressive firmness. In case 8 the lower fragments of the tibia were severely comminuted into the ankle joint with very little firm bone to which the plate could be anchored. Case 12 presented a mutilated hand with severe scar tissue and 1 inch loss

³ Burrows H. G. Treatment of Ununited Fractures by Bone Graft Without Resection of the Bone Ends. *Proc Roy Soc Med* 33: 157-160 (Dec.) 1939.

of bone in the lower end of the radius. Union was successful even though persistent sinuses were present.

Examination of the grafted region after removal of the plate has revealed bony union of the graft to its bed. The surface under the plate has been found to be living fibrous tissue of periosteal consistency.

Microscopic study of a section taken transversely through the graft and cortex of the fragment shows that the graft becomes adherent to the host bone with new vessels forming a cytogenetic relation between the new tissue introduced and the bone tissue in the neighborhood.

SUMMARY AND CONCLUSIONS

The advantages of a plated osteoperiosteal graft are

- 1 The metal plate is very dependable
- 2 The simpler procedure is more often justified in delayed union
- 3 There is less violent trauma by bone sawing in obtaining and fitting the graft
- 4 There is less bulk to cover up than in full thickness grafts
- 5 It affords an earlier grafting operation on compound fractures with old scars and sinuses
- 6 It renders earlier passive motion
- 7 When reduction of the fragments is not necessary, the intermediary callus need not be removed
- 8 Resulting osteogenesis compares favorably with that obtained with the full thickness graft

605 North West Tenth Street

ABSTRACT OF DISCUSSION

DR. LEO S. LUCAS, Portland, Ore. The importance of retaining the periosteum on the bone graft is still a controversial point. In operating on dogs and using otogenous grafts with the periosteum retained, and others in which the periosteum was removed, Pollock concluded that no advantage is gained by the retention of the periosteum in bone grafting operations. It was his opinion that removal of the periosteum from the graft results in the production of a more active periosteum from the surrounding connective tissue and that the scarification of the surface in the removal of the periosteum liberated osteoblasts from the graft itself. It is my feeling that the most important factor is the preservation with as little trauma as possible of the periosteum at and surrounding the fragments to be grafted. Where possible, all soft tissues should be left intact in order to preserve the blood supply that is so important in the process of repair. I agree with Dr. McBride that, unless it is absolutely necessary to redress the fragments in order to obtain proper alignment, the fibrous tissue between the ends of the bone should not be disturbed, and this applies to any type of bone grafting procedure used. The ossification of these tissues is rapid during osteogenesis. Because of the difficulty of properly securing osteoperiosteal grafts, many of us have felt that the massive onlay or inlay grafts were superior. While the osteoperiosteal method may be sufficient to produce the necessary osteogenic material, this type of graft has been difficult to apply with proper fixation of the fragments, which is so important in the healing of an ununited fracture. Dr. McBride has shown the feasibility of using the graft to better advantage, insuring excellent fixation to the affected parts and the possibility of using it in early cases in which the more extensive procedures might be accomplished with more risk. It offers a method that has been successful in his hands, is comparatively simple in application and conforms to good surgical principles.

DR. REXFORD L. DIVELEY, Kansas City, Mo. We are indebted to Dr. McBride for this most interesting presentation. I can commend to you his exhibit in the Scientific Exhibit in which he has most of the presented cases illustrated with plates. I was not impressed in the study of this exhibit with

the fact that the periosteal graft is entirely responsible for the union or the osteogenesis. I was impressed however, with the fact that the union takes place as the result of the fixation. Therefore it is my feeling having seen many grafts being held by band and by wire and by other metallic pressure, that the massive onlay, or the massive inlay osteoperiosteal graft, carefully and firmly held by two or four metallic screws of the vitallium type, will not only give fixation but will also give certainly a great deal more osteogenesis than will the periosteal graft which is being hugged or crushed by a plate.

DR. EARL D. McBRIDE, Oklahoma City. I purposely left out of this paper the various discussions that I knew might arise with regard to periosteum versus bone in osteogenesis. It is an old subject and we have heard it discussed many times. I agree with Dr. Diveley that the immobilization is an essential factor in this method. In the interim of different cases I have used a plate without the graft in two or three instances. I am impressed that they do not produce the same results as when I use the osteoperiosteal graft. As a matter of fact I operated again in 1 case and used the osteoperiosteal graft because of failure of union. Consequently it is immaterial to me whether the improvement is due to the fixation or to the osteoperiosteal graft. There is 1 case in the exhibit in which I show that the graft has been fixed with screws alone and the result is just as good as when I used the metal plate over the graft. So there is no argument in that respect. The point that I made about this entire discussion is that with the metal plate for fixation, which is absolutely dependable and which is not subject to absorption as is the cortical graft together with the sulfonamide drugs which we now have enables us to secure union in some of these chronically infected compound fractures that otherwise would be kept in a plaster or other immobilization for months and months. Now we can proceed to take the risk of surgery in nonunion of old compound fractures, with the confidence that we have the fragments fixed and that we can get the patient to respond to function much earlier. That holds true with delayed union. We usually put on casts and wait two or three months then put on another cast, thinking that perhaps the forearm bone or humerus would finally unite and we would wake up finally to find a stiff elbow or stiff fingers. Now, with a good fixation of the osteoperiosteal graft under the plate I am able to remove immobilization much sooner with a better function of the elbow and fingers. So I have developed full confidence in this method and thought it worth while to present the method for your consideration just from these certain points of view and have purposely omitted arguments regarding the various controversies of bone graft versus periosteum and healing of bone tissue.

More or Less Continuously Bored—The mode of life of the majority of American women married to men of average or better than average incomes is more deleterious to their physical and functional well-being than any except the extreme degrees of privation and drudgery. In the first place they have so little to do that they are more or less continuously bored. Boredom leads to restlessness, restlessness to mental and nervous hypertension which expresses itself in functional neuroses, irritability, introspection and the expenditure of a tremendous excess of nervous energy in the performance of any physical or mental task. All of this leads to nervous fatigue and neurasthenia. The average woman who has driven her children to school, planned the day's menu, instructed her servants and repaired some trifling damage to her wardrobe must go to bed after lunch and rest before engaging in the arduous task of an afternoon at the bridge table. Knowing the exhaustion which attends the performance of such things she feels that she cannot survive the exertion attendant on a game of golf or tennis, a swim, or a ride on horseback. As a result her muscles become flabby, fat accumulates, the general tonus is reduced to a minimum, the functional activities of the body are impaired and functional neuroses reign unopposed.—Cooke Willard R. *Essentials of Gynecology*, Philadelphia, J. B. Lippincott Company, 1943.

THE PLACENTAL TRANSMISSION OF PROTECTIVE ANTIBODIES AGAINST WHOOPING COUGH

BY INOCULATION OF THE PREGNANT MOTHER

PHILIP COHEN, M.D.

AND

SAMUEL J. SCADRON, M.D.

NEW YORK

Whooping cough is the dread contagious disease of infancy. During the first two years of life it is the cause of more deaths than measles, diphtheria, poliomyelitis and scarlet fever combined.¹ Against the latter diseases the baby usually is born with a passive immunity transmitted by the mother through the placenta.² Since this is a passive immunity it endures for only approximately six months. Such does not seem to be the case with whooping cough.

Pediatricists not infrequently encounter cases of whooping cough in early infancy. The figures on the incidence of whooping cough in the infant vary from 8 to 18 per cent of the total incidence of whooping cough at all ages.³ This is clinical evidence of the frequent lack of immunity in the newborn.⁴ At present there are few data on the humoral immunity of the average adult against whooping cough. This is explainable because it is only in the last few years that proper immunologic tests for whooping cough have been devised. Without proper and sufficient data as to the immunity of the adult female, immunity of the newborn baby against whooping cough in respect both to frequency and to degree can be only conjectured. Thus Holt and McIntosh⁵ state that natural susceptibility to whooping cough seems to be equal at all ages and little or no immunity is conveyed in utero, regardless of whether or not the mother is immune. Some believe that natural immunity to pertussis does not exist and that no natural immunity is transmitted from mother to child.⁶ On the other hand, Knoepfelmacher,⁶ in Pfandl and Schlossmann's system, states that a congenital immunity to whooping cough can be accepted derived from previous pertussis of the mother. Sauer¹ speaks

little of this subject in Brennemann's System of Pediatrics except for quoting Bordet as believing in transient congenital immunity. It seems that there is no unanimity of opinion on this subject.

The human placenta is of the hemochorionic type in which a single layer of chorionic and endothelial cells separates the fetal from the maternal blood.⁷ To all intents and purposes, there is here a semipermeable membrane obeying the physicochemical laws of semipermeable membranes.⁸ The size of the molecules determines what passes across and what fails to pass the placental barrier.⁹ In general, antibodies and not antigens are able to filter through from the mother's blood to the baby's blood.⁹ Thus it has been demonstrated that the titer of diphtheria antitoxin is approximately the same in the mother's blood, the cord blood and the placental blood.¹⁰ The same holds true of the other antitoxins such as tetanus.¹¹ It is well known that the blood group of the baby may not be well established for several weeks because of the passage of the mother's blood agglutinins into the fetal blood.¹² Immunity against scarlet fever, measles and poliomyelitis for the first half of the infant's life is conferred on the baby through the antibodies of the mother's blood by way of the placenta. The newborn baby has also been shown to have, at least in many instances, antistreptolysins,¹³ antistaphylococci and other bacterial antibodies similarly passively transmitted by the mother.¹⁴ The same probably holds true of antibodies against all organisms which are already preformed in the mother's blood during pregnancy.¹⁵

According to Needham, antigens as a class unlike antibodies, do not pass through the placental barrier. There are certain exceptions, however, for typhoid, malaria, pneumonia¹⁶ and rheumatic fever, among other diseases,¹⁷ have been described in newborn babies. In these instances we are dealing with a disease process which probably alters the capillaries on both sides of the placenta effecting an abnormal exchange. Ratner

This work was aided by a grant of the William S. Paley Foundation. From the service of the Jewish Maternity Division of the Beth Israel Hospital.

The social service department and the nurses of the hospital aided in this investigation with willing cooperation and untiring efforts.

and his colleagues¹⁸ however, have presented evidence that allergenic antigens can traverse the normal placental membrane and actively induce antibody production. It may be possible then for the antigen in the mother's blood to be transmitted to the fetal blood in which event active immunity will result as well as passive immunity.

Chart 1—Showing close correlation of protective titers. The baby's titer is higher in each instance. The shaded column indicates the mother's protective antibodies and the unshaded column the baby's protective antibodies.

As shown earlier, whooping cough in infants is accompanied by a high mortality.¹⁹ It is for this reason—this apparent lack of immunity of any nature against whooping cough—that efforts have previously been made actively to immunize young infants, but the results have been disappointing, for immunity did not result from inoculations with the Sauer vaccine in young infants in the dosage of 80 billion, beginning at 1 month to 2 months of age.²⁰ The young infant apparently has not the capacity to form antibodies against the whooping cough bacillus antigens. In fact, the most modern opinion is that the very young infant is a poor antibody producer against all antigens.²¹ Young infants inoculated with the Sauer vaccine, unlike older infants similarly inoculated, contracted whooping cough on exposure as frequently as those uninoculated. Since active immunity has not been successful in these young infants at this most dangerous age period for whooping cough, the idea came to one of us (P C) to create active immunity in the pregnant mother in the last trimester of pregnancy, hoping that the antibodies so formed would pass the placental barrier and induce passive immunity in the baby.

Our idea was to inoculate the pregnant mother with a potent pertussis bacillus vaccine in the fifth or sixth month of pregnancy. The vaccine we chose is one prepared by Mishulow of the New York Laboratories, which has proved potency and which we have used in previous work with satisfactory results.²² Our plan was to administer the vaccine at intervals of two weeks

for six injections, totaling 150 billion organisms. This timing was chosen because it was shown by Mishulow and Wilkes and their associates²³ that the highest titer of protective antibodies was found in the blood of vaccinated children approximately two months after vaccination. In order to minimize reactions, the first dose was 10 billion, the second 20 billion and the other four doses 30 billion, given subcutaneously in one or both arms. In many instances the full dose of 150 billion organisms was not administered either because of the tardy initial presentation of the pregnant mother or because absence from the clinic threw off the timing of our injections, which were aimed to terminate a month or two before the expected date of delivery. At times deliveries occurred earlier than the calculated date, upsetting our time table, but delivery beyond the expected date had little effect on the results.

The reactions of the inoculated mothers were less severe than those obtained when children are inoculated with the Sauer vaccine. Elevation of temperature was encountered only twice in our first hundred cases. Soreness and tenderness in the inoculated area was a feature in almost every case. A persisting lump, sometimes for days, was a common occurrence. There were times when the arms were so sore that the woman could not use them for two or three days. The local reactions were very similar to those generally encountered in children, but the systemic reactions were less frequent and far less noticeable. There were no abscesses and no persistent nodules. It was apparent to us that the inoculations had no effect on the pregnancy or delivery. There were no premature births or postpartum complications which could be attributed to the inoculations. The babies thrived and did as well in the hospital as did the babies of uninoculated mothers serving as a control series.

Before the injections were begun 10 cc of blood was taken for the titration of antibodies, which also served the purpose of a control measure. These data will be included in a separate article by Mishulow and her co-workers. At the time of delivery 10 to 15 cc of blood was taken from the mother and the umbilical

Chart 2—Illustrating lack of correlation of protective antibodies with agglutinins and complement fixation. Equivalent heights for agglutination 1/200 is indicated by vertical shading, complement fixation 0.01 cc, by horizontal shading and protective antibodies 100 per cent by unshaded column.

cord, which represents the baby's blood. These bloods were titrated for immune bodies. At intervals of six to nine months equal amounts were to be taken from mother and baby for a retitration of immune bodies to enable us to study the duration of any immunity.

actively or passively induced. A group of unimmunized mothers and their babies were similarly bled and their blood quantitated for the same immune bodies. These served as a control group.

The specific immune bodies studied in this investigation were agglutinins, complement fixing antibodies

determine the presence of another infection, in the event of such a finding the mouse was eliminated from the calculations. In all mice that were inoculated with the culture H pertussis was recovered from the heart's blood in the first four days of the test unless the plates were contaminated by other organisms that invaded the blood post mortem when the mice died during the night.

The agglutination results were recorded in terms of the highest dilution of the serum that showed distinctly visible clumps. Indistinct or no agglutination in 1:10 dilution of the serum was recorded as negative. Complement fixation was recorded in terms of the smallest amount of the serum that gave complement fixation under standard conditions. Incomplete or no fixation in 0.02 cc of the serum was recorded as negative.

Because agglutinins and complement fixing antibodies are not necessarily correlated with immunity,²⁶ special attention was given to the study of protective antibodies. Investigation of other tests which have been used to appraise immunity in whooping cough, such as cutaneous tests,²⁷ opsonophagocytosis studies,²⁸ the antitoxin content of the serum²⁹ and the protection of mice by the serum against a multiple lethal dose of live

and protective antibodies. The laboratory tests were carried out by Miss Mishulow and her assistants at the New York City department of health. Her method of testing for these antibodies was the same she used in her studies of the immunologic response in cases of pertussis and in vaccinated children.³²

In the test for protective antibodies groups of mice were inoculated with 0.2 cc of the serum intramuscularly nineteen to twenty hours previous to the intraperitoneal injection of a multiple killing dose of virulent *Hemophilus pertussis* suspended in 1 cc of 4 per cent mucin. At each test similar groups of mice were inoculated with a known positive serum and with the test doses of the culture without serum; these served

* This woman was tested after delivery

† N T = not tested insufficient serum

inadequate 5 or more mice were employed. The results of these tests are reported in a fractional form; thus 0/9 indicates that 9 animals were used and none survived; 8/10 indicates that 8 out of 10 animals survived. The numerator of the fraction signifies the number of animals that survived and the denominator signifies the number of animals that were used.

Our intention was to use 10 un inoculated women and their infants as control cases. Unfortunately a wave of incidental infection killed most of the animals used for this purpose so that we were left with only three

mothers gave a history of whooping cough in their childhood and the other 3 had a doubtful or negative history of previous pertussis. Of these 6 babies 1 had a fair amount of protective antibodies, 1 had a good titer of such antibodies and 1 had questionable protection. All these bloods revealed no agglutinins or complement fixing antibodies. Thus of 9 babies of un inoculated mothers, 2 or 3 showed some degree of protective antibodies (none with a really high titer) and none of their serums showed the presence of the other antibodies tested for.

We consider protection excellent when the great majority of the mice are protected by the serum. We consider protection good when close to half of the animals are saved by serum. Protection is fair when 30 per cent of the animals survive. Twenty-nine women have thus far been selected for the immunologic studies from a group of 167 women inoculated with the vaccine in doses from 80 to 150 billion. By these standards of immunity of 29 cases 27 showed a very high titer, all definitely positive results. Of 27 babies tested, including 1 set of twins, the titers were equally high. In the case of E A and P B, the babies had a higher titer than the mother. The babies' figures seemed to indicate a slightly higher titer than the mothers'. This may or may not be significant.

The agglutination and complement fixation reactions did not exactly correspond with the titers of protective antibodies. Thus the serums of 8 subjects were poor in the former antibodies yet yielded high protection. The twin babies who had high protective antibodies, had little or none of the other antibodies tested. This is in keeping with previous work done on this subject.²²

The tests were performed at intervals of from one to eight weeks after vaccination. We have some patients with an even longer interval after the last inoculation, but their serums have not yet been studied. The length of the interval seemed to make no difference in the height of immune bodies of the mother and the newborn baby. Whether it will affect the duration and the persistence of the antibodies is a matter for future study. The same probably holds true of the dosage. Although almost all of our patients were vaccinated with 120 to 150 billion organisms some were vaccinated with only 80 to 90 billion. One woman vaccinated with 80 billion and 2 with 90 billion yielded as high a protective titer as those inoculated with the larger doses. Whether these antibodies will persist as long as in those cases in which the smaller dosage was given is questionable. The ages of our group of women varied from 19 to 36 years of age. The age factor and multiparity seemed not to play a role in the production of immune bodies. The previous history of whooping cough seemed not to play a role in the production of antibodies. Only 3 of the 29 women were sure that they had whooping cough, about a third were doubtful. There was no correlation between their initial titer of antibodies and the antibodies formed by vaccination. There was no difference in the data of this group and of the group who were certain that they had never had whooping cough.

RESULTS AND COMMENT

As far back as 1879 attempts have been made to immunize a newborn baby by inoculation of the pregnant mother against a specific disease.²² In the case of syphilis, the inoculation of the pregnant mother to prevent or cure congenital syphilis is a universal measure.²³ Lichty, Slavin and Bradford²⁴ attempted, as they put it, to increase resistance against pertussis in newborn infants by immunizing the mother during pregnancy. They confessed their failure. An analysis of the data revealed the following facts. The injections were given at two week intervals in the last six weeks of pregnancy. The total dose administered was

20 to 25 billion. Thus the dose was inadequate and too late for antibody formation which reaches its climax between one and two months after the last inoculation. The test for immunity which they employed, cytophagocytosis of the blood, has distinct limitations and has been abandoned by them in favor of mouse tests.²⁵ Their figures showed no increase in cytophagocytosis of the inoculated mother's blood. Granting the validity of the test, they found no increased immunity in the mother, so that there were no antibodies transferable to the baby through the placenta. In rabbits it has been proved as in babies, that the very young rabbit could not be immunized against pertussis,²⁶ but by the inoculation of pregnant rabbits antibodies were formed which were transmitted to the newborn rabbit.²⁷ This would seem to be the animal counterpart and confirmation of our work.

In a recent article it was found with the opsonocytophagic test,²⁸ that there was a correlation in the opsonizing power of mothers and their infants. This has previously been suggested by Bradford and Slavin,²⁵ yet Kendrick, Gibbs and Sprick,²⁸ with the same test, reported that the blood of newborn infants has virtually no phagocytic powers and is not correlated with the mother's reactions. Rambar and his co-workers²⁹ found that in a large series of premature infants there is a strong reaction up to 2 months of age and then a decline, suggesting a placental transfer of circulating antibodies against whooping cough. Our work is more in agreement with the latter findings. We have found that when a mother has a definite titer of antibodies against whooping cough she transmits it to the baby in about the same titer. This was true of 100 per cent of our series after the mothers had been inoculated with a sizeable dose of vaccine during the last trimester of pregnancy.

Mishulow and her co-workers³⁰ found that 15.2 per cent of children and adults who had a negative history of pertussis had pertussis protective antibodies. They also found in a study of the preimmunization bleedings of women who were studied in this investigation that 31.2 per cent of them had these antibodies before they were vaccinated.⁴⁰ If we can assume, as would seem likely from our investigations, that these antibodies are transmitted from the pregnant adult to the baby, a definite proportion of babies may be born with some immunity against whooping cough. In the few cases that we have studied we have found on two or three occasions protective antibodies in the cord blood, but more investigations are needed to establish percentage incidence. In the meantime, it may be conservative to assume that a small percentage of babies, perhaps 15 per cent to 25 per cent, are born with passive immunity of uncertain duration but that the great majority have no protection against whooping cough. This fits in well with known clinical facts. Sauer's¹ and Top's³ studies point to no great difference in susceptibility between the younger and the older infants if vaccination has not been performed. This is an important point, for the high mortality in the susceptible infants, which is a

common pediatric experience, was the fact which led us to attempt our prophylactic measure. The need for the protection of the infant against this dread disease is therefore nearly as great as was anticipated.

Recently a similar investigation was performed with diphtheria immunization.⁴¹ Diphtheria lends itself readily to such studies because techniques are available for the titration of antitoxin in the blood and there is a good cutaneous test as an index of immunity, namely the Schick test. With such methods past studies of diphtheria have shown a high correlation between the antitoxin content of the bloods of the mothers and their babies.⁴² Such studies have revealed also that in large cities close to 90 per cent of mothers are immune to diphtheria as are their babies.⁴³ Yet in the recent Chicago study of this subject more than 50 per cent of mothers at term were found to be Schick positive and to have an antitoxin content of blood inadequate to constitute an effective immunity against diphtheria. Because of this, the pregnant mothers were inoculated with diphtheria toxoid in the latter part of pregnancy. There resulted a close correlation between the increased antitoxin titer of the mother's blood, the cord blood and the infant's blood. If this work is verified by further studies, previous estimates of diphtheria immunity in the newborn will have to be revised and measures taken to protect the newborn baby against diphtheria. In a discussion of this paper, mention was made of the great need for a similar project to confer protection on the newborn baby against dangerous whooping cough. Since our work was already in progress, this was an interesting statement to us.

Does the presence of a high titer of protective antibodies in serum signify definite immunity in the human being against whooping cough? While this question cannot be categorically answered in the affirmative, there is much evidence to make this a logical assumption. The convalescent from whooping cough, in most instances, has a serum rich in protective antibodies.⁴⁴ After proper immunization with vaccines the serum becomes rich in protective antibodies.⁴⁵ It has been demonstrated that this hyperimmune serum as well as convalescent serum is of great value in preventing whooping cough in unimmunized contacts⁴⁶ and is even of great aid if employed in suitable doses in the treatment of whooping cough itself.⁴⁷ Small amounts of such serums are remarkably effective in protecting animals against what is otherwise an overwhelmingly fatal infection from live pertussis bacilli injected intraperitoneally.⁴⁸ There is ample evidence in the literature

now that individuals inoculated with suitable doses of a proper vaccine have a high degree of immunity against whooping cough.⁴⁹ Correlated with this immunity is the presence of protective antibodies in the blood of the vaccinated individuals.⁵⁰ These facts all point to the conclusion that protective antibodies, if not the sole mechanism of immunity against whooping cough, are a reliable index of immunity. The question can be answered finally only by a follow-up study of the fate of infants and children, vaccinated and unvaccinated, with and without protective antibodies when actually exposed to intimate contact with whooping cough. We are doing this now, but this is an investigation which will take years and large numbers of cases before an unequivocal answer can be obtained.

What is the nature of this immunity and how long will it last? Judging by the close correlation of the titers between mothers and babies, this transplacental immunity is most likely of a passive nature. On the other hand, the higher titer in a few babies may indicate a passage of antigen conferring added active immunity on the baby. It must be recalled that there have been several instances in the literature of antigens passing the placental barrier.⁵¹ This is not merely an academic question, for passive immunity will be of short duration—from a few weeks to a few months—while active immunity will last for a much longer time. In addition, boosting doses, which has proved to be a successful technique,⁵² is more apt to be of value if the immunity has an active factor. Thus, if one finds that at 6 months of age the baby is rapidly losing his immunity, a further injection of 30 billion bacilli can be given and the dose repeated every six months or yearly. This work we have already begun.

CONCLUSIONS

1 Since whooping cough is such a serious disease in young infants, an attempt was made to immunize newborn babies by vaccinating the pregnant mother with a whooping cough vaccine in the last trimester of pregnancy.

2 In this we have been successful, judging by the presence of immune bodies.

3 The total dose we advise is 150 billion, given at intervals of two weeks beginning at the sixth month of pregnancy. The last injection is to be given six weeks to two months before term.

4 The systemic reactions after vaccination were few and not severe. The local reactions were common, at times very painful, not serious and sometimes lasted as long as a few days.

5 There were no discernible effects on the course of pregnancy, on delivery or on the baby. There were no miscarriages or premature births that could be attributed to the procedure.

6 In 29 instances immunologic studies were performed on the serums of babies and mothers after

vaccination, with particular emphasis on mouse protection tests

7 In every case the protective titer was raised to a very high level, which was almost quantitatively transmitted to the baby

8 We have reason to believe from this evidence that these babies were born with immunity against whooping cough

9 Further studies are being made as to the duration and persistence of these antibodies in both babies and mothers

10 A small control series of 9 babies of uninoculated mothers were studied immunologically. None revealed agglutinins or complement fixing antibodies, but 2 or perhaps 3 yielded a fair titer of protective antibodies

11 There is, then, some evidence that a definite percentage, perhaps between 15 and 25, of babies may be born with some immunity against whooping cough

12 A biologic follow-up is being carried out to correlate the exposure to and the incidence of whooping cough in the inoculated group as compared with an equally large uninoculated group

1175 Park Avenue—993 Park Avenue

ABSTRACT OF DISCUSSION

DR. SAMUEL J. SCADRON, New York. Our idea was to inoculate the pregnant mother with a potent pertussis bacillus vaccine in the fifth or sixth month of pregnancy. I want to say a word with regard to the effect of this vaccine on the pregnant mother. We have studied only 29 cases immunologically but we have inoculated 167 mothers. In other words, we immunized 167 mothers. There were 90 multiparas and 77 primiparas. The average dose injected was 120 to 150 billion. Previous history of whooping cough in our patients was unknown to 15. A hundred had whooping cough in early childhood. There were 37 positive histories and 15 were doubtful. The types of delivery were not affected by the pertussis vaccine. We had 2 cases of toxemia, which I did not attribute to the injection of the vaccine. I myself watched these cases ante partum and during the postpartum period and found that the vaccine was absolutely innocuous. But the mothers were protected against whooping cough, and this most likely had a beneficial effect on the babies.

DR. WILLIAM L. BRADFORD, Rochester, N. Y. Several years ago I was interested in the placental transmission of antibodies in pertussis as tested by the opsonocytaphagic reaction of the blood. It was observed that in certain newborn infants a high titer existed. When this was true the mother almost always possessed a high titer likewise. Dr. Lichty and Mrs. Slavin were generally able to increase the titer of the baby by injecting the pregnant mother with vaccine during the last trimester of pregnancy. This work was not extended because it did not seem at the time, to be of practicable application. By using the mouse protective method, Drs. Cohen and Scadron apparently have obtained equally good or better results, suggesting that the opsonocytaphagic reaction and the mouse protective antibody may give comparable results as methods of testing humoral immunity to pertussis.

DR. PHILIP COHEN, New York. Owing to limitation of time, I could not go into the presumptive proofs that the protective antibodies in the serums which were induced by inoculation of the pregnant mother conferred immunity. I did mention some of the evidence which Dr. Bradford just presented and some additional evidence in the literature wherein protective antibodies, if not the chief factor in immunity, is a reliable index of immunity in the newborn baby and in any one who has those protective antibodies. I might add that 29 cases are not a small group to be studied because the number of mice we used in these tests amounted to at least 2,000. At least 30 mice are required for each case, so that the technic is prodigious. Dr. Muckenfuss and Miss Mishulow did this work, without which nothing could have been accomplished.

REPAIR OF TRAUMATIC GAPS IN NERVES

DAVID BODIAN, PH.D., M.D.
BALTIMORE

The requirements for functional regeneration of divided nerves are complex and exacting. This is at once evident when it is realized that under the most favorable conditions of repair, by means of primary suture of accurately approximated stumps, the original function of the nerve is never completely restored. The many problems and clinical difficulties involved in connection with nerve injuries have been the subject of numerous investigations and publications, almost two thousand being cited by Pollock and Davis.¹ Quite recently the experimental data and theoretical considerations on the long investigated problems of nerve regeneration have been reviewed critically and extensively by Young.² Since an understanding of the complex series of processes which accompany unaided regeneration of severed nerves is basic for any consideration of methods of closure of gaps too wide to be bridged by the unassisted normal process, a brief summary of some of the essential details, as now understood, may be helpful at this point.

1 Physical union between the separated stumps is accomplished, when the gap is not too great, by proliferating Schwann cells, most of which grow out from the distal stump, and by fibroblastic tissue. The parallel orientation of the elongated Schwann cells and fibroblasts in the union scar is of importance in controlling the direction of growth of fibers regenerating from the central stump, since these fibers may otherwise be lost in futile outgrowth into the collagenous tissue surrounding the nerve. If for any reason the fibroblastic tissue predominates in the union scar or interrupts the continuity of the bands of Schwann cells, such a connective tissue scar as it hardens may form a serious barrier to the regenerating nerve fibers.

2 Although the peripheral stump is capable of receiving new fibers for at least as long as seventeen months after injury, and the central stump retains the power to send out new fibers for much longer periods, the formation of a favorable union scar is prejudiced by delay in approximation of the stumps because of reduced outgrowth of Schwann cells from the cut surfaces, so that fibrous tissue predominates in the union scar.³ This is one strong indication for primary or early repair as well as the probability that too long a delay in reinnervation of the end organs, especially in muscles, may permit irreversible regressive changes to occur in these end organs.⁴

3 The union scar must supply a full caliber bed of proliferating Schwann cells through which a majority of the regenerating fibers of the central stump, and their branches, may pass to the distal stump. This newly formed bed must allow as much cross sectional space as occurs in the distal stump to permit increase in caliber of the newly formed fibers and their myelination. The "maturation" of the regenerating fibers

appears to be as important for return of functions as the successful attainment of proper end organs by these fibers.⁵ It is likely that proper vascularization of the tissue bridging the gap between the stumps is also of importance.

The repair of traumatic gaps which cannot be closed in spite of mobilization of the nerve, rerouting, or articular movement is now attempted by means of stretching operations in two or three stages, nerve crossing, or nerve transplantation. Without discussing the advantages or disadvantages of these methods, it is proposed to describe a new method designed to make possible a simple primary or secondary repair of large nerves by means of a single stage operation.

METHOD

The stumps of the injured nerve are freed from scar tissue, and the ends prepared as for end to end suture. After mobilization of the stumps as much as possible, a cylindric segment of the distal stump, embodying the nerve sheath and the underlying outer bundles of nerve fibers, and somewhat longer than the gap to be bridged, is prepared and moved proximally into apposition with the central stump. The sleeve-like extension from the peripheral stump can be prepared in two ways, the choice being determined by circumstance. It can sometimes be freed distally by a circular incision in the peripheral stump which severs only the outer nerve sheath and peripheral bundles and then pulled proximally along the central core of the distal stump (figs 1 and 2). However, when the inner sheaths of the nerve offer too much resistance to such a "sliding sleeve extension," the sleeve-like extension can be dissected free from the inner core of nerve bundles, following the line of incision shown in figure 3, and moved proximally into apposition with the central stump as shown in figure 4. With this procedure it is possible to avoid severing the main blood vessel in the sheath of the peripheral stump.

With the sliding sleeve extension, sutures need be placed only at the line of apposition with the central stump, in the manner of end to end suture, the calibers of the sleeve extension and of the central stump being comparable. The absence of a distal suture line, such as occurs with ordinary grafts of nerves, is an advantage of obvious importance.

Sutures in the case of the dissected sleeve extension are placed as shown in figure 4. Fixation to the core of the distal stump can be obtained by suturing sheaths only, if the dissected sleeve has been made sufficiently long. In this case, as with the sliding sleeve extension, the central end of the core of the distal stump is protected from invading collagenous tissue by the enveloping sleeve of nerve tissue.

The advantages of the sleeve extension methods, which have been used successfully in experiments in rhesus monkeys, are: 1 Uncomfortable postures of limbs, as in nerve stretching operations, are avoided. Also avoided is the risk of overstretching the nerve with possible intraneural vascular interference or retrograde injury to fibers.⁶ 2 No other nerve is deprived of function as in the case of nerve crossing or nerve autotransplant operations. 3 The repair procedure is confined to the site of the nerve injury. 4 Except for the junction with the normal central stump, which is

soon crossed by regenerating fibers, there is no place where invading fibrous tissue can form a transverse barrier to outgrowing nerve fibers. In the case of transplant operations, for example, the distal union scar may require later resection to permit fibers which have regenerated to this point to pass into the distal stump.⁷ 5 In autocable transplant operations involving the preparation of segments of a normal cutaneous nerve in the form of a bundle which is sutured to the proximal and distal stumps of the injured nerve of the same patient, the outer fibrous sheath of each segment of transplanted nerve becomes incorporated in the substance of the repaired nerve, and thus fibrous tissue may scarify to the extent of becoming rigid and preventing adequate enlargement and maturation of newly formed fibers within. In the case of the sleeve extension operations, excessive fibrous tissue is not incorporated into the interior of the repaired segment of nerve. 6 If repair by means of sleeve extension is done without too great delay after injury, the proliferative activity of the Schwann cells in the distal stump is utilized not only to accomplish union with the central stump but also to create a new and favorable

1 Large peripheral nerve with traumatic gap irreducible by tension rerouting or postural shortening. 2 Same with gap closed by means of sliding sleeve extension from distal stump. 3 Nerve with gap, showing line of incision for preparation of dissected sleeve extension. 4 Gap shown in 3 closed by means of dissected sleeve extension. Both types of operation are completed by contact approximation of sleeve graft with central stump and the placing of additional sutures through the sheaths at the plane of junction as in end to end suture.

bed for regenerating fibers within the cavity of the cylindric sleeve extension. The filling of this cavity with longitudinal columns of Schwann cells, along which regenerating fibers grow readily, compensates, as will be shown, for the initial deficiency of nerve substance within the sleeve extension. Moreover, the cavity of the sleeve extension is protected from invasion by fibrous tissue. Similarly, columns of Schwann cells migrate around the exposed core of the distal stump from the cut surfaces of nerve fascicles and increase the effective caliber of the nerve in this region.

When a delay of several months has occurred preceding operation for repair, a sleeve extension can be prepared in similar fashion from the proximal stump, after resection of the neuroma since the distal stump at this time may be of stiffer consistency and its Schwann cells may have reduced proliferative potencies.

The defects or difficulties of the sleeve extension operations, theoretical or real, are as follows: 1 The caliber of the distal stump is reduced by the preparation

⁵ Gutmann E, Gutmann L, Medawar P B and Young J Z. The Rate of Regeneration of Nerve J. *Exper Biol* 19 1444 (May) 1942

⁶ Stokey Byron. Surgical and Mechanical Treatment of Peripheral Nerves, Philadelphia W B Saunders Company, 1922

⁷ Davis Loyal and Cleveland D A. Experimental Studies in Nerve Transplants. *Ann Surg* 99 271 283 (Feb) 1934

of the sleeve extension. As just pointed out, this is partly compensated for by Schwann cell proliferation, so as to allow for an adequate bed for most of the regenerating fibers. 2 The preparation of the sleeve extension may be complicated by branching of the distal stump in the course of the sleeve segment. If the branches are small they may be severed close to the main trunk and sutured to the nearest point of the exposed core of the distal stump after the gap in the parent trunk has been closed. If the branches are large it may be advisable to prepare the sleeve extension from the central stump. It is also possible to close the gap by using sleeve extensions from both the proximal and distal stumps. 3 The organization of the empty fiber sheaths of the distal stump is disrupted by the sleeve extension operations. It is obvious that this is no more serious than in transplant operations and is less serious than in nerve crossing. Whether functional recovery is seriously prejudiced thereby is unlikely, and in any case this point can be settled only by the results of practical experience.

EXPERIMENTS

Experiments with the method described on the large nerves of the extremities of rhesus monkeys are in progress and will be described in detail when completed. The primary criterion of adequate repair is considered to be the return of movements which cannot be replaced by the action of uninvolved synergistic muscles. At the time of writing several animals have shown good, and still continuing, recovery of lost digital movements three to four months after resection of 2 cm of tibial or peroneal nerves, in the midfemoral region, followed by sleeve extension repair. Seven tibial nerves and two peroneal nerves are included in this series. Similarly, earliest recovery of finger movements following median or radial nerve resection and repair in the midhumeral region, has occurred after five to six months in single cases. In the case of the radial and peroneal nerves the control nerves on the opposite side, in which a resected 2 cm segment was sutured to the proximal and distal stumps in the original position, have shown recovery at about the same time. Observations are being continued.

Microscopic study of the tibial nerve of a control animal killed two months after sleeve extension repair of a 3 cm defect with the sleeve prepared from the proximal stump has revealed that a great number of newly regenerated fibers had already traversed the zone of repair and had entered the distal stump, into which some fibers had penetrated for a distance of 17 mm, or a total distance of regeneration of about 47 mm. The sleeve extension was filled with loose schwannian tissue, well vascularized and conducting regenerating fibers. The exposed core of the central stump, from which the sleeve extension had been prepared, had increased in caliber, partly by condensation of connective tissue surrounding it. This connective tissue contained many parallel bundles of apparently vigorously regenerating fibers, which had already entered the neural tissue of the sleeve extension. The histologic picture of the region of repair, which grossly at autopsy appeared as a smooth, fusiform swelling of the tibial nerve not densely adherent to surrounding tissues, indicated that the region of repair had gained substance, effective as a bed for regenerating fibers, from both proliferated Schwann cells and from endoneurial and perineurial tissue. All these tissues can

apparently adapt effectively in the maintenance of regenerating axons and in the eventual formation of a new nerve.

SUMMARY

A method described for the closure of irreducible traumatic gaps in nerves in a single operation, utilizing only the tissue of the injured nerve, may be of value in the repair, preferably early, of certain cases of injury to large nerves. The principle may also have application when used in combination with other methods of closing gaps, such as mobilization, rerouting or postural shortening and subsequent stretching. Early results of experiments in rhesus monkeys indicate that initial functional recovery with this method occurs at about the same time as recovery in nerves repaired with full thickness autografts. The degree of functional recovery finally attainable with this method remains to be determined.

SUBDURAL HEMATOMA AND EFFUSION AS A RESULT OF BLAST INJURIES

FIRST PRELIMINARY REPORT

LIEUTENANT COMMANDER WALTER D ABBOTT

MC-V(S), UNITED STATES NAVAL RESERVE

LIEUTENANT (j g) FLOYD O DUE

MC-V(S), UNITED STATES NAVAL RESERVE

AND

LIEUTENANT (j g) WILLIAM A NOSIK

MC-V(S), UNITED STATES NAVAL RESERVE

Our purpose in this report is to bring forth a compilation of war injuries which differs from trauma sustained in civilian life. This condition could be overlooked and the individual patient relegated to chronic invalidism or discharge from service with a diagnosis of a functional disorder, such as psychoneurosis or war neurosis.

Subdural hematoma is not an uncommon complication of craniocerebral trauma usually the result of a direct blow to the skull, varying in degree of intensity. It has been shown that the hematoma occurs following the rupture of small veins, either between the layers of the dura or between the inner surface of the dura and the arachnoid.

Because of the poor absorptive action due to a scanty blood supply to these membranes, the hematomas seldom disappear spontaneously. The blood contained in the subdural effusion or hematomatous mass undergoes chemical disintegration, giving rise to an entrapped liquid of higher protein content than is found elsewhere in the head. In an effort to correct this condition cerebrospinal fluid is drawn from the subarachnoid space by osmosis, and the size of this fluid mass, gradually enlarged, produces a progression of symptoms. A liquid type of lesion has been referred to as subdural hydroma because, at operation, very little old blood is encountered, instead there is an escape of large amounts of xanthochromic fluid. The protein content of this fluid is higher than cerebrospinal fluid, which is indicative of stasis.

From the Neuropsychiatric and Neurosurgical Services U S Naval Hospital Oakland Calif

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U S Navy. The opinions and views set forth in this article are those of the writers and are not to be considered as reflecting the policies of the Navy Department.

We have observed a number of blast injuries sustained in action. They are the result of injury by a nearby exploding bomb on ship or land or may be the result of a concussion wave subsequent to a sinking ship or a depth bomb while the patient is in the water.

Examination of the fatal cases at autopsy reveals multiple hemorrhages throughout the body, varying from petechiae to frank bleeding.

It is our opinion that in some instances in which there is no direct blow a severe concussion from a bomb explosion at variable distance away will lead to either a small subdural hemorrhage or a sudden rent in the arachnoid, permitting a temporary escape of the cerebrospinal fluid into the subdural space. It is felt that the arachnoid eventually effects a closure in the tear. The mass increases in size because of osmosis due to the increased protein content of the entrapped fluid, which may be mixed with small amounts of blood.

The patients present a history of exposure to severe concussion, loss of consciousness for a period varying from a few minutes to several days, persistent headaches, memory loss and irritability. It is seldom that many positive neurologic signs are present, and what few are evident are not pronounced. The most common findings are a slight facial palsy, a transient hemiparesis and occasionally a transient change in reflexes.

The most pronounced symptoms are persistent headaches, usually generalized (increased on exertion and often nocturnal), a history of coma, syncope or convulsions which did not exist prior to the blast and a definite departure from a stable personality. Further studies from the psychiatric point of view are presented in the second preliminary report.¹

The number of cases reported is small, but they are presented in the hope that there will be a more widespread recognition of this entity. There have been cases of bilateral effusion of small amounts of old blood and several ounces of xanthochromic fluid that we have chosen to call a subdural effusion in contrast to a true subdural hematoma, which is characterized by an

Diagram of subdural space

accumulation of a large amount of blood. In only 1 case did both conditions occur: there was a large hematoma over the right cerebrum and 3 ounces of xanthochromic fluid on the left.

When such a lesion is suspected after a careful history has been obtained, thorough neurologic and psychiatric study will indicate the necessity for pneumo-

encephalography. If a hematoma or effusion is present in the subdural space, a characteristic filling defect is observed over the cerebrum with an occasional distortion of the ventricular system.

It is noted that in performing encephalography the total protein content of the cerebrospinal fluid is increased.

Conceptual quotient 120 Interpretation: Superior intelligence no intellectual impairment

REPORT OF CASE

R. T. G., private first class, aged 24, on active duty against enemy forces, on Sept. 27, 1942, was thrown to the ground by a nearby shell explosion. He was dazed, had difficulty in returning to his landing boat and remembered nothing for two days.

Following this period, severe generalized headache was present and became progressively worse with exertion. The cephalalgia was of such intensity that it would awaken him at night. He complained of vertigo and loss of memory.

General and neurologic examinations were negative. The blood pressure was 130/80 mm. of mercury, the pulse rate being 72. Roentgenograms of the skull were negative. On the Otis self-administering test of mental ability, higher examination, form B, he scored 59, intelligence quotient 117. The results of the Shipley-Hartford Retreat test of intellectual impairment are given in table 1.

Although these results were not conclusively abnormal, it was considered that there was a discrepancy between the Otis and Shipley tests and the clinical impression of the patient's original ability. It was concluded that there was a superior intelligence with evidence of intellectual dysfunction exclusive of the frontal lobes.

The persistent headaches and psychiatric findings led to a suspicion of a subdural lesion, and on November 27 pneumoencephalographic study was performed under tribromethanol in amylene hydrate anesthesia. The cerebrospinal fluid was under pressure of 200 mm. of water. One hundred and twenty cc. of this fluid was replaced with an equal amount of air.

The total protein of the fluid was 30 mg. per hundred cubic centimeters, the cell count was 4 and the Kahn reaction was negative. The colloidal gold curve was negative.

Roentgenograms indicated a filling defect over the left lower parietotemporal area and were significant of a space-occupying lesion.

On December 7, under tribromethanol in amylene hydrate anesthesia, a perforator opening was made into the left superior temporal bone and a large subdural effusion was removed. The postoperative condition was uneventful and there has been a definite improvement in all his symptoms.

The Shipley-Hartford Retreat test was given on December 17 with the results presented in table 2.

¹ Abbott W. D., Due F. O. and Nosik W. A. Subdural Hematoma and Effusion as a Result of Blast Injuries. Diagnosis by Psychiatric Examination. J. A. M. A. to be published in the next issue.

OPERATIVE TECHNIC

Tribromethanol in amylene hydrate is administered rectally thirty minutes before surgical operation. A small incision is made over the indicated superior temporal area and a perforator opening is placed in the skull. The dura is tense and often bluish. When this is incised there is an escape of several ounces of either old blood or xanthochromic fluid. A small rubber catheter is placed over the temporal lobe and led out through the incision.

Closure is effected in layers with interrupted cotton sutures. If a bilateral defect is noted in the encephalogram a similar procedure is carried out on the opposite side. One hour after the patient leaves the operating room a lumbar spinal drainage of 30 cc of cerebrospinal fluid is performed with the dressing removed. Air is aspirated through the rubber catheter by negative pressure into the subdural space. The head dressing is replaced and the patient is taken to the x-ray room where postoperative roentgenograms reveal the size of the preexisting lesion. This follows the technic described by Woods and Kahn² to prevent postoperative adhesions.

The drain is removed the next day and the sutures within forty-eight hours.

The patient is up on the third day and returns to duty in six to eight weeks.

There have been no operative fatalities in the group operated on and most patients will be returned to duty. There have been 10 cases, 5 of which were bilateral. Seven patients had subdural effusions and in 2 instances subdural hematomas occurred.

SUMMARY

There is a group of patients suffering from the concussion effect of a nearby shell, bomb or underwater explosion who develop an accumulation of fluid in the subdural space. The chief complaints are headache, minor neurologic findings, and pronounced change in personality. Recognition and removal of either a subdural hematoma or an effusion will relieve these symptoms.

The Medical Adjective—A good example of the overworked medical adjective is marked, which is used to express so many qualities as to have become almost meaningless. It replaces great, copious, abundant, large, tangible, evident, perceptible, clear, unmistakable, decided, pronounced and others. In many cases its effect is purely emotional and has the same significance as the word 'bloody' in other fraternities. The word 'definite' has come to have a special meaning in our hands; the reverse of its content in general use. When a doctor says 'there was enlargement of the spleen' we cannot misunderstand him; when he says 'there was definite enlargement of the spleen' he introduces an element of doubt, almost as if he was surprised at the finding and perhaps not quite sure of it. In any case he had added nothing to his description and, if he uses the phrase to three of his colleagues, one will believe that the spleen was considerably enlarged, another that the enlargement was slight while the third, with perhaps greater insight, will assume the size of the organ to be within normal limits. The essence of professional description is to convey the same meaning to all who read or listen, if this be so then the word 'definite' and its objectionable partner 'very' might well be omitted from medical idiom.—The Decay of Medical Language, editorial, *New Zealand M J* 41: 235 (Dec) 1942.

Clinical Notes, Suggestions and New Instruments

A METHOD FOR INTRODUCING SULFANILAMIDE INTO THE PERITONEAL CAVITY

MAJOR ROBERT A WISE
MEDICAL CORPS UNITED STATES ARMY

The value of sulfanilamide in the peritoneal cavity in intra-peritoneal infection is well established. It is particularly important to place the crystals at the site of severest infection at which the highest concentration is desirable.

The site of severest infection is usually the point of greatest contamination, which in cases of perforated retrocecal or pelvic appendicitis, may be high in the right lumbar gutter or low in the pelvis. Unfortunately, it may be difficult or impossible to deposit the crystals at the desired point in patients operated on through a McBurney incision.

The introduction of the crystals high in the right lumbar gutter or low in the pelvis presents a mechanical problem which can be simply solved by the following procedure:

PROCEDURE

The gauze packing in a cigaret drain is pulled back from one end for a distance of 2 inches and sulfanilamide crystals are poured into this end of the drain. A sponge forceps is applied to the open end of the drain below the sulfanilamide holding the crystals in place (fig 1). After the drain has been inserted into the desired location, the forceps is removed. The crystals leave the end of the drain and are dispersed in the adjacent tissue. By this one maneuver sulfanilamide has been introduced to the point of greatest infection and a drain has also been placed to this site (fig 2).

Fig 1—Showing cigaret drain with gauze packing pulled back and sulfanilamide crystals in the end of the drain. Sponge forceps holds crystals in place and assists in introducing drain into the desired location.

Fig 2—A drain with sulfanilamide crystals high in the right lumbar gutter. B drain with sulfanilamide crystals low in the pelvis.

Additional sulfanilamide is placed, in the usual manner, in that part of the peritoneal cavity directly exposed by the incision.

TWO ADDITIONAL CASES OF TRAUMATIC WINGED SCAPULA OCCURRING IN THE ARMED FORCES

MAJOR CHARLES U HAUSER
MEDICAL CORPS ARMY OF THE UNITED STATES
AND

MAJOR WILLIAM T MARTIN
MEDICAL CORPS, ARMY OF THE UNITED STATES

In a recent issue of THE JOURNAL Ifield and Holder¹ reported a case of traumatic paralysis of the serratus anterior muscle seen in their service at Camp Callan, California. The winged scapula in their patient resulted from trauma incidental to carrying a full knapsack. Two cases of paralysis of the serratus anterior muscle were seen at the Station Hospital, Langley Field, Virginia, in September. Because of the rarity of this condition and the unusual cause of these 2 cases, the findings seemed important enough to record in the medical literature.

CASE 1—Private W Q, aged 26, admitted to the Station Hospital Sept 24, 1942, complained of a recurrent dislocation of his left shoulder on lifting heavy objects. He gave a history of having his left shoulder slip "out of place" when he lifted a garbage can on Sept 16, 1942 while working with

Fig 1 (case 1)—Winging of left scapula.

a prison detail. Although right handed, he attempted to lift with his left hand. As he elevated the weight to shoulder height he experienced a burning sensation over the coracoid process radiating to the tip of the scapula. At the same time he felt his shoulder "slip out of place." He was relieved of heavy duty for one week, but when he attempted further lifting the shoulder repeatedly "slipped out of place." On September 25 severe pain developed in his left arm and neck and he was hospitalized. On admission he presented the classic picture of winging of the scapula on forward and lateral elevation of the left arm with no limitation of motion in or about the shoulder joint. Muscle and neurologic examinations were essentially negative except for an isolated paralysis of the serratus anterior muscle. The rest of the admission work-up was noncontributory. Treatment consisted of an application of heat to the shoulder with the arm supported in a sling. The patient was hospitalized for three months before sufficient power returned to his serratus anterior muscle to enable him to fix his scapula.

CASE 2—Sgt T E C, aged 20, was admitted to the hospital Sept 3 1942 after an automobile accident in which his car was overturned and crushed under a Pullman car. The patient was pinned for two hours in the front seat of his car in an

inverted position with his left arm jammed against the door and most of his body weight resting on his left shoulder. When extricated from the wreck, he was hospitalized and found to be suffering from multiple bruises of both hips and the left flank, fractures of the transverse processes of the second and third lumbar vertebrae and complete musculospiral

Fig 2 (case 1)—Oblique view of winged scapula showing lower division of trapezius to be unaffected.

Fig 3 (case 2)—Winging of left scapula.

paralysis of the left extremity, in addition to winging of the left scapula. Examination of the shoulder revealed winging on forward and lateral elevation of the shoulder, with the left arm farther from the midplane than the right on complete elevation. It was possible to assist in complete elevation by thrusting forward and upward on the angle of the scapula.

Released for publication by the War Department Manuscript Board which assumes no responsibility, other than censorship for the contents of this article.

¹ Ifield F W and Holder H G. Winged Scapula. Case Occurring in Soldier from Knapsack. J A M A 120 448 (Oct 10) 1942.

There was complete paralysis of the serratus anterior muscle and lower division of the trapezius with an asymmetrical rounding of the posterior axillary fold as the chest was viewed

Fig. 4 (case 2)—Scapula immobilized in an elevated position by means of body cast with elbow cradle

Fig. 5 (case 2)—Anterior view showing detail of body cast

from the front. Under conservative management the musculo-spiral palsy cleared up within a week's time but the serratus paralysis continued, and it was felt necessary to place the

muscle at complete rest by elevating the scapula and fixing it to the posterior wall of the chest. To secure this immobilization, a body cast was applied with a padded cradle for the left elbow. The cradle exerted a continuous upward thrust on the left shoulder, elevating and fixing the scapula and placing the serratus at rest in a relaxed position. With the application of the cast and the institution of heat and massage to the shoulder the patient soon noticed greater strength and continued to regain muscle power. He remained in the hospital seventy-two days before his muscle power was strong enough to allow him to return to duty.

Many explanations have been offered to account for traumatic winging of the scapula. In all, a violent contusion or stretching of the nerve causes sufficient dissociation of continuity of the fibers to account for a paralysis which has, at best, a guarded prognosis. The nerve arises from the posterior roots of the fifth, sixth and seventh cervical nerves and courses through the scalenus medius muscle, uniting within or on the surface

Fig. 6—Detailed view of padded elbow cradle

of the muscle, where it is relatively exposed for a short distance. In the first case, a contraction of the scalenus medius muscle in fixing the chest cage incidental to forceful lifting damaged the nerve. By contracting, the scalenus may have immobilized the nerve, causing it to be stretched as the shoulder completed its arc against resistance. In the second case the palsy resulted from prolonged pressure against the shoulder. The mechanism of pressure on the clavicle is not clear because the nerve is protected by the axillary nerve and brachial plexus as it courses behind the clavicle. Perhaps, in the second case as well, the scalenus, contracting to support the chest, pinched the nerve long enough to cause a palsy.

The exact mechanism of the disorder in the 2 cases of traumatic paralysis of the serratus anterior muscle here presented is not clear. That the mere lifting of a heavy object or the wearing of a full pack can give rise to prolonged or permanent disability should arouse the interest of all entrusted with the care of the armed forces. We make no claims for originality in presenting the detailed pictures of a simple and expedient immobilization cast. In addition to immobilization, heat and massage are the best means of promoting return of muscle power.

HANDBOOK OF NUTRITION XXIII

MEDICAL EVALUATION OF NUTRITIONAL STATUS

H D KRUSE, MD
NEW YORK

(Concluded from page 591)

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed

STATES OF VITAMINOSIS

From the concept of deficiency states it may be seen that an avitaminosis includes all forms, degrees and stages. Under this classification the classic deficiency disease, as originally described, represents the severe acute state. Such a term as latent or subclinical state, which has been objectionable to some investigators, is no longer necessary. It is seen to be a broad state comprising the mild acute and mild chronic conditions. It is preferable to use the more specific designation corresponding to the actual condition. The severe chronic state has had no previous designation.

The concept also explained the various courses in the pathogenesis of these states. Whereas the description thus far has indicated that any one of the several states exists alone, actually conditions are often more complex. Through the usual vicissitudes, particularly over years, the process usually changes in velocity, intensity and even direction. To mention one or two more common of the various eventualities, an acute subsides into a chronic process, or a mild or severe chronic state, once established, constitutes a base on which is superimposed a mild or severe acute process. Undoubtedly in the outbreaks of classic deficiency diseases the severe acute form is very frequently engrafted on a preexisting mild or severe chronic base. But these do not represent all the possible changes in rate, stage and intensity which a process may undergo. It may have a very variable and tortuous course. As a result, a mild or severe acute process in any stage may be seen with a mild or severe chronic form in any stage. These combined states add to the number of categories which must be borne in mind. Thus a deficiency disease may exist in any one of the following states: mild acute, severe acute, mild chronic, severe chronic, as well as mild or severe acute superimposed on mild or severe chronic, each in a particular stage. It cannot be overemphasized that the combined states are very prevalent, perhaps the most prevalent.

Scattered observations in the literature on deficiency diseases are in accord with one or another point in the concept. In addition to the reports already cited on the mild acute state, others have taken cognizance of the chronic state. In describing various forms of rickets, Eliot and Park⁶¹ mentioned early mild, florid and mild chronic. Their description of the course of these respective states may be interpreted in terms of intensity and time.

Furthermore, the literature records the characteristic difference between the acute and chronic forms in response to treatment. Eliot and Park⁶² remark that in one form of rickets the complete cure is slow. It has also been noted that in treatment of polyneuritis in animals, the acute fulminating type disappeared very speedily in a few days, the chronic type very slowly, in fact, only after many months.⁶³

A few investigators have mentioned a chronic state of pellagra in contradistinction to the more dramatic acute form.⁶⁴ Some changes in the tongue in pellagra have been described erroneously as part of the acute process, whereas they were really chronic in nature.⁶⁵ In scurvy produced in animals, Tozer⁶⁶ differentiated the chronic from the acute form on a time basis. She stated that the chronic form varies in severity according to the degree of deprivation of vitamin C. Using a different terminology to express intensity, she described mild and severe degrees for both the acute and chronic forms. Recognizing these various states, Hojer⁶⁷ employed still another nomenclature. Ferrario⁶⁸ and Boyle⁶⁹ also produced acute and chronic scurvy in guinea pigs. Similar observations have been reported on experimental athiaminosis.⁷⁰

The severe acute state is the form on which almost all clinical attention to deficiency diseases has hitherto been focused. Historically this form, presenting a grave problem, was the first to be recognized, consequently the recorded knowledge on its symptoms, signs and pathology predominate in the literature. Similarly in experimental work, where the objective was to demonstrate the existence of new vitamins or to assay foods, animals were suddenly shifted from an optimum natural to a deficient "purified" diet in which every trace of an essential had been as far as possible removed. Naturally the severe acute form of deficiency ensued. A few investigators have given attention to the mild acute state.

61 Eliot Martha M and Park E A Rickets in Brennemann's Practice of Pediatrics Hagerstown W F Prior Company Inc 1938 vol 1, chapter 36 pp 62-65 87 92 94

In the past the chronic state of deficiency diseases has received only sporadic and scant notice. Paradoxically, however, chronic manifestations have been frequently seen but their relation to nutrition was not recognized. The mild chronic state has been undetected or neglected. Generally the mild acute, mild and severe chronic states, the most common states among the population, have not been recognized and differentiated. The very prevalent combination acute with chronic has not been fully appreciated as such and the constituent forms have not been distinguished and separated.

Since the chronic state of deficiency diseases has not been commonly recognized, it is worth while to mention some of its characteristics. Its essence is time. For persons this is age. The longer persons live, the more chance they have to incur changes and to have them develop to an advanced state. Consequently chronic changes are seen with greater frequency and in the latest stages with increasing age. I have noted this in avitaminosis A, ariboflavinosis, aniacinosis and avitaminosis C.

In the past these chronic alterations have been called senile changes with the implication that senility causes them. But senility per se is not responsible for them. That has never been a satisfactory explanation. Not all elderly persons show the changes. On the other hand, they occur in children.⁷¹ Time not senility, is the essential point. And time does not start the changes, it simply is a dimension over which they progress. They are specific avitaminoses in a state of chronicity, due usually to dietary deficiencies running over a period of years. Their prevalence and severity vary with the number and degree of deficient diets and therefore with the economic level. Most important of all they are reversible, yielding slowly but completely to appropriate therapy.

This rate of response is another characteristic peculiar to the chronic process. Whereas acute changes respond with considerable promptness, chronic changes recede very slowly. In acute changes we are accustomed to expect improvement with dramatic rapidity. Actually, some of rapidity is more apparent than real. For one thing it is a relative matter, the more pronounced the acute, the more spectacular is a given degree of improvement. Often removal of late signs constitutes supposed rapid cure of an acute deficiency. Obviously this is far from complete cure. But it is mainly because the relief of symptoms, the first event, is so prompt as to be striking. If judged solely by freedom from symptoms, the therapeutic response of an acute process is rapid. But when judged by complete restoration of all tissue changes, as seen by the biomicroscope, response in the acute condition is not quite so spectacularly quick as it is reputed. Nevertheless, response is infinitely more rapid in the acute than in the chronic state.

METHODS OF APPRAISAL

With this concept of the various states in mind, it is appropriate to consider the various new methods that have been proposed for use in appraising nutritional status. They comprise biochemical, microbiologic, biophysical (most of which are functional), special clinical and morphologic, including biomicroscopic. At once

it should be stated that they pertain to different aspects of deficiency diseases and yield dissimilar kinds of information.

Most of the biochemical methods are designed to determine the concentration of the vitamins in the blood and urine. One kind of method is based on the reaction of a vitamin to yield a colored or fluorescent substance which, under suitable conditions of intensity and stability, may be estimated. Another kind depends on the reaction of a vitamin with a dye which is carried partially or entirely to completion so that the residual color or end point, respectively, may be determined. For each reaction there are usually several methods, differing only in the size and preparation of the sample and means of estimating the concentration of the vitamin. These reactions are rendered quantitative by colorimetry, fluorimetry and titrimetry, and objective by spectrophotometry or photoelectrometry.

Microbiologic methods depend on the failure of a particular micro-organism to grow in the absence of a specific vitamin. The concentration of the essential is assayed by the degree to which it stimulates growth. Or it is measured by its accelerating action on a biologic process such as fermentation.

For information bearing on the state of nutrition with respect to an essential the biochemical and microbiologic methods may be applied in four ways. The concentration of the vitamin in blood is determined on specimens collected before breakfast. For a vitamin that is excreted in the urine, the amount there may be ascertained from one or more specimens collected after an interval of several hours from the last meal or from a twenty-four hour sample. In general, low values for the vitamin in either instance point to a recent diet deficient in the essential. Other procedures comprise measuring the response to a test dose of the vitamin by determining either its absorption from the blood or its excretion in the urine. Here for both blood and urine the methods differ in the amount of vitamin administered, the number of samples to be taken and the time of drawing them. Usually the blood technic includes initial or pretest, peak and subsequent basal determinations. Most of the excretory methods restricted to the collection of one or a few specimens are designed to cover the period of maximum response, some call for a twenty-four hour sample. These urinary response procedures are the saturation, tolerance or load tests. Low values by the procedures involving response to a test dose indicate not only that the previous dietary intake has been deficient but also that the reservoirs are depleted. These several procedures yield information of different character because they bear on such different aspects as transport, storage, utilization and excretion of the vitamin.

Two of the vitamins also occur in the blood as constituents of coenzymes. Hence concentration of that is also determined by the foregoing types of methods. Also chemical methods are used to determine the accumulation of metabolites in the blood or to detect the presence of an abnormal pigment in the urine as the result of a vitamin deficiency.

Among the biochemical methods on blood, the formation of a blue color when vitamin A is treated with a chloroform solution of antimony trichloride⁷² provides

⁷¹ Since it was obviously inappropriate to apply the term senile changes to children the equally unsuitable name presenile changes was used.

⁷² Carr, F. H. and Price, E. A. Colour Reactions Attributed to Vitamin A. *Biochem. J.* **20**: 497-501, 1926.

the means for determining vitamin A concentration.⁷³ Oxidation of thiamine to thiochrome and measurement of the intensity of the latter's fluorescence⁷⁴ forms the basis of estimating the thiamine level.⁷⁵ Another method for detecting avitaminosis B₁ depends on the increase in values for disulfite binding substances⁷⁶ or pyruvic acid⁷⁷ signifying failure in decarboxylation from deficiency in thiamine.

The level of co-carboxylase (thiamine diphosphate ester or thiamine pyrophosphate, which functions as a coenzyme or carboxylase in conversion of pyruvic acid into carbon dioxide and acetaldehyde) may be determined in three ways: differential solubility of thiochrome and thiochrome pyrophosphate,⁷⁸ enzymatic conversion of co-carboxylase into thiamine⁷⁹ or manometric determination of the carbon dioxide released during an enzymatic process in which pyruvate is the substrate.⁸⁰ Goodhart and Sinclair⁸¹ have pointed out that estimation of thiamine or co-carboxylase in whole blood is not a reliable means of detecting possible deficiency of thiamine. They regard lowered concentration of thiamine in the plasma as furnishing more trustworthy evidence.

For determination of nicotinic acid or nicotinamide in the blood, the reaction of these substances with an aromatic amine and cyanogen bromide⁸² provides several methods.⁸³

A number of chemical methods have been devised for assaying ascorbic acid in the blood,⁸⁴ most of them based on the reduction of 2,6-dichlorophenol-indophenol,⁸⁵ a few of methylene blue.⁸⁶ The application of these methods in various procedures has already been reviewed.⁸⁷

Methods for determining calcium,⁸⁸ phosphorus and phosphatase⁸⁹ levels are well known. Disturbances in these components are associated with rickets.

Plasma or serum proteins may be determined by a convenient colorimetric method.⁹⁰ The significance of alterations in these blood constituents, particularly albumin, has been described at length.⁹¹

Nutritional anemia due to iron deficiency is microcytic and hypochromic in type. Although microcytosis may occur alone, diminution in hemoglobin concentration of the blood is usually an early sign. In the comprehensive examination in private practice or the hospital, a complete hematologic examination is desirable. But in surveys on a large scale the objectives and possible results must be weighed against the limitations in time and personnel and the magnitude of the work. It is doubtful that it would be justifiable to conduct a thousand blood counts when only a few will yield low values. Rather, determination of hemoglobin concentration would seem to be sufficient for most surveys.

The results from surveys demonstrate the usefulness and adequacy of this single procedure.⁹²

Here is a technic known for a long time but too often neglected or conducted by instruments capable of revealing only wide abnormalities and yielding such errors that they could not reveal slight deviations or reported in terms of variable standards,⁹³ with variable allowance for normal range. Osgood⁹⁴ has admonished that "all hemoglobin estimations should be reported in grams per hundred cubic centimeters and the method used should be stated. Otherwise the great variation (138 to 173) in the number of grams of hemoglobin taken as 100 per cent in different methods and the enormous differences in the accuracy of the methods will make correct interpretation of the results impossible."

Furthermore, in view of indications from other deficiency diseases, perhaps more consideration should be given to slight or marginal changes in hemoglobin concentration. Some agreement on standards, recognition that one level as a standard will not suffice for all ages⁹⁵ and perhaps narrowing of the present wide range accepted as normal are items in need of consideration. Moreover, to remove errors inherent in most instruments, the method should be performed whenever possible on a photoelectric colorimeter.

For assaying the vitamins in urine, the biochemical methods are based mostly on the same reactions as in blood. In the estimation of thiamine the thiochrome⁹⁶ or diazotized P-aminoacetophenone reactions is utilized. Riboflavin excreted as uroflavin is measured by

a fluorometric method.⁹⁶ Nicotinic acid derivatives may be determined by their reaction with cyanogen bromide in the presence of a suitable amine.⁹⁰ Another method for detecting aniacinosis depends on the appearance of a fluorescent substance.¹⁰⁰ Several methods for determination of vitamin C, based on the reduction of 2,6-dichlorophenolindophenol¹⁰¹ or methylene blue,¹⁰² vary in technical points and procedures for appraising the state of vitamin C nutrition. A very complete literature on this has been reviewed.⁹⁷

Of the microbiologic methods on blood, the estimation of thiamine concentration¹⁰³ was based on the necessity of this substance for growth of the fungus *Phycomyces blakesleanus*.¹⁰⁴ That thiamine was found to increase the rate of fermentation¹⁰⁵ was utilized in another type of method.¹⁰⁶ The indispensability of riboflavin for lactic acid bacteria¹⁰⁷ led to a method for determining the concentration of this vitamin in blood by use of *Lactobacillus casei*.¹⁰⁸ Factor V, a growth factor for

Haemophilus parainfluenzae, has been shown to be replaceable by two coenzymes (cozymase or codehydrogenase) which contain nicotinamide. Hence this micro-organism has been used to measure the cozymase content of the blood.¹⁰⁹ But it is stated that determination of coenzyme I offers little diagnostic information in borderline cases of deficiency disease.¹¹⁰ The fermentation test has been used in determining the thiamine content of urine.¹¹¹ Riboflavin in the urine has been estimated by bacterial assay with *L. casei*.¹¹² With dog's urine the growth of *Bacterium paratyphosae* and *H. parainfluenzae* has been used to assay the content of nicotinic acid¹¹³ and factor V respectively.¹¹⁴

In an attempt to simplify the method of estimating tissue saturation with vitamin C, Rotter¹¹⁵ introduced the intradermal test whereby a small amount of dichlorophenol-indophenol dye is injected beneath the skin and the fading time is recorded. The validity and reliability of the test have been questioned, principally because its values do not correspond with plasma levels of vitamin C.¹¹⁶ Recently this skin test was found to be more closely related to the urinary excretion test for saturation with vitamin C.¹¹⁷

Biophysical methods have been designed to elicit under stress and to measure by special instruments functional or structural impairments attributed to avitaminoses. Methods for detection of visual dysadaptation to darkness were in use long before they were proposed as a means of recognizing early avitaminosis A.¹¹⁸ Following Fridericia and Holm's

experimental production of night blindness in rats on an A-deficient diet,¹¹⁹ Jeans suggested that dysadaptation be used as an index of avitaminosis A.¹²⁰ Several instruments for measuring dark adaptation have been devised.¹²¹ These instruments have been shown to have technical faults and the test itself has been criticized on its subjectivity, lack of fixed threshold and standards.¹²² The extensive literature on the subject has been presented.¹²³ Furthermore, under actual field conditions in three surveys the most recent models gave disappointing results, since a single measurement of the visual threshold was found not to be a reliable indicator of mild avitaminosis A.¹²⁴ The fault seems to lie not in the instruments or in their ability to detect dysadaptation but in the inference that dysadaptation appears as a sign of early or mild avitaminosis A. The latter inference has been questioned.¹²⁵

Measurement of capillary resistance to pressure, another biophysical method, has been applied in appraising vitamin C status. Like dysadaptation, capillary fragility was originally described in association with a variety of pathologic states.¹²⁶ In 1914 Hess described tests with positive pressure showing impaired capillary resistance in scorbutic infants.¹²⁶ Using the same procedure and counting petechiae, Gothlin suggested that capillary resistance or fragility be used as a measure of vitamin C status.¹²⁷ Meanwhile, a method for measuring capillary fragility by application of negative pressure had been developed and used in many diseases,

but not with reference to vitamin C undernutrition¹²⁸ Later it was adapted to appraising vitamin C status¹²⁹

Several investigators have found no correlation between the values for capillary resistance and the plasma concentration or urinary excretion of ascorbic acid¹³⁰ More important, the method yielded a high degree of variation in values Its limitations have been fully discussed¹³¹ It is useful for recognizing somewhat severe acute scurvy But it does not detect early or mild avitaminosis C, for capillary fragility does not appear in this state¹³²

For many years tests of neuromuscular response to galvanic stimulation were employed in clinical medicine Although the method was first applied to adults,¹³³ its use was soon limited to the diagnosis of "latent" tetany in infants and children¹³⁴ It indicated, therefore disturbances in calcium or vitamin D, or both Its wide variability in older children and adolescents and the availability of methods for determining the content of calcium in the blood led to almost complete abandonment of the neuromuscular method

Morphologic methods include the x-rays, the microscope and the biomicroscope with simple inspection for definite lesions New aids in the recognition of slight changes in the skeleton in early scurvy by x-ray examination have been furnished¹³⁵ At the same time it has been pointed out that subperiosteal hemorrhages in infantile scurvy may not be visualized on the roentgenogram until administration of vitamin C induces deposition of calcium salts in the periosteum¹³⁶

According to Eliot and Park¹³⁷ "the x-rays give more accurate information concerning the existence of active or healing rickets than physical examination, but for early diagnosis they have limitations" Furthermore, it has been shown that there may be conflict of opinion as to the presence or absence of evidence of rickets in individual films¹³⁸

By differential staining and microscopic examination the demonstration of keratinized epithelial cells in the scrapings from the corner, the nose and the mouth, and in secretions from the trachea, bronchi, kidneys and vagina has been proposed as confirmatory diagnosis

tic evidence in suspected cases of avitaminosis A¹³⁹ It will be noted this procedure was not asserted to be a means of early detection

Gross and biomicroscopic examination of the conjunctiva, ocular limbus, tongue and gums reveals all forms, degrees and stages of avitaminosis A, ariboflavinosis, amacinososis and avitaminosis C respectively¹³⁸ In each specific tissue site selected for observation the pathologic process not only appears early but persists and changes in correspondence with the course of the avitaminosis Furthermore, the site is readily accessible to observation Although very much may usually be seen grossly in moderate and severe states, the biomicroscope is exceedingly sensitive in revealing the very early and slight tissue changes It allows low grade states, whether prolonged or not, to be detected In fact, it is essential for observation of these states The slightest change and the closer it approaches perfection, the more the microscope is needed From this examination, status is expressed for both acute and chronic processes, each in terms of stage and degree

CHOICE OF METHODS

Which kind of method is best? The answer depends on the purpose for which the method is to be used The outstanding objective is the appraisal of nutritional status in the population, to be conducted in schools, industry, business organizations, private practice, hospitals, public health centers and fields surveys Certain requirements inherent in this objective must be met The test for a particular deficiency disease should be simple, easy, quick and reliable Preferably it should be objective rather than subjective Practical considerations require that it be feasible The tests for individual deficiencies should be adaptable to combination in a system of examination which retains all the qualities enumerated Furthermore, such a system should not require too many instruments or large personnel When one instrument can be used for several tests there is a distinct advantage The system must also be applicable to all ages, adults as well as children No age group should be overlooked It should be noted that many methods in the past applied exclusively to children Malnutrition in adults has been a neglected subject Important as is nutrition in the growth period, it is equally important in the later decades Recognition of the chronic state gives emphasis to this statement Finally, in order to characterize malnutrition it is essential not only to detect the occurrence but also to establish the status of each deficiency disease It is particularly important that the system of evaluation should be effective in detecting the states in which deficiency diseases actually exist most frequently in the population Most of the deficiency states in this country are chronic, in all degrees and with or without an accompanying mild or severe acute process¹³⁹ Hence the system should permit detection of all forms, stages and degrees

The several kinds of tests vary in meeting these requirements Biochemical and microbiologic methods on blood, despite their usefulness and essentiality for many purposes, have disadvantages for application in surveys They are laborious, are time consuming and require a laboratory with trained personnel Unfortun-

nately too, as a means of appraising nutrition they have very narrow limitations beyond which they are misleading.

In the evolution and recession of an avitaminosis, the change in concentration of a vitamin in the blood and the alteration in tissue state are not synchronous. They are on different time schedules. Blood is the labile transport system. If in the initial attack the tissue were normal and the blood value were low, such a value would be significant. But practically this condition is the least frequent in the general population, indeed relatively unprevalent, and would be found mostly in infants and preschool children. With widespread prevalence of avitaminoses, particularly in the chronic form, and their establishment early in life in most persons, a perfect state in the tissue is relatively infrequent. It should not be forgotten, furthermore, that the biomicroscopic examination of tissue is sensitive in detecting the very early and mild tissue changes, indeed all states. Hence the blood method as a primary screen for the appraisal of vitamin C status has in reality a very limited range of application.

Once chronic changes have appeared—and this is the common eventuality and the most prevalent state—the blood values may be unreliable. The chronic process in the tissue recedes exceedingly slowly, almost infinitesimally, on any sustained improvement in diet and only very slowly under persistent therapy. In contrast, values on the concentration of a vitamin in the blood reflect very sensitively the recent dietary habits¹⁴⁰ as well as other conditioning factors. They may change not only with season¹⁴¹ but also within shorter periods, they may fluctuate. Blood values rise rapidly in reflecting changes in improved intake, such as from seasonal or occasional dietary improvement, but with no noticeable effect in the chronic process in the tissue. A sustained satisfactory blood level resulting from adoption of a satisfactory diet or taking of low potency maintenance tablets, now so popular, is not accompanied by any appreciable improvement in an existing severe chronic pathologic condition in the tissue. Potent therapy will produce maximum blood levels and entirely restore bodily saturation in several weeks but will completely repair the slightest chronic tissue lesion only in months. Here a high blood level will be maintained over the many months while the tissue lesion is receding but is, of course, still abnormal. Temporarily or consistently, therefore, the blood values may, under these several circumstances, be moderate or high without demonstrable recession in the existing chronic lesion. In any of these instances the blood value would indicate a satisfactory nutritional status while the tissue would be pathologic. Manifestly, appraisal from the blood value alone would be entirely misleading.

It should be clear that there is no necessary high correlation between data derived by different methods on the same deficiency disease. They provide information on different aspects and states of the disorder. Unfortunately, this fact has not been appreciated. Rather, it has been thought that various methods applied to the same deficiency disease should yield similar data. On this basis it has become the practice to test the validity of a method by comparing its results with blood values. This procedure is entirely unsound. When it is remembered that blood values shift rapidly

and may fluctuate intermittently, while tissue changes very slowly, there should be no expectation of identical results.

An example demonstrating these points is particularly revealing. With the development of accurate methods for determining the concentration of ascorbic acid in blood and urine analyses have been conducted on these fluids, after a fasting period or a test dose, as a means of appraising vitamin C status. There has been a strong trend toward general acceptance of the results from these procedures as the true index of bodily status with respect to vitamin C. Indeed, the reliability of other methods of appraisal has been gaged by comparison with blood values as the criterion. Yet Greenberg, Rinehart and Phatak¹⁴² cautioned

“the estimation of the reduced plasma ascorbic acid is only a measure of the immediate nutritive or metabolic level relative to vitamin C and is dependent on recent dietary habits to a large degree. Although it is an index of the vitamin C nutrition at the time of the test, in a single case a low level does not imply tissue injury or scurvy (either clinical or subclinical). The latter results from the operation of suboptimal or low metabolic levels over some period of time. Conversely a good or high level would not indicate that deficiency had not operated to produce tissue injury in the past.”

In line with this statement Crane and Woods¹⁴³ studying an acute outbreak of scurvy in children by comparing gingival condition with ascorbic acid concentration in plasma both in the autumn and in the following spring, found that 7 of 17 children with consistently high ascorbic acid values on both occasions had gingival inflammation at one or the other examination while 14 of 25 children with inflammation of at least six months' duration had high values on one or the other occasion. A similar comparison of ascorbic acid values with the states of the gingival lesions which I³⁸ conducted in a low income group, with a more sensitive method of detecting and more rigid criteria of rating pathologic conditions in the gums, revealed an even less constant relationship. These results, far from demonstrating that the blood level is a trustworthy criterion for comparison of other methods, show that it has serious restrictions as a method for appraising vitamin C status. Determination of the excretory level and bodily saturation tests, whether from serial analyses on blood or on urine, also have these limitations.

In several hands, routine examination by the biophysical methods has failed completely to detect early or even moderately intense avitaminosis¹⁴⁴. Either the disturbances, e.g. disadaptation and petechiae are not pronounced enough in their early stages to be detected or they are late manifestations.

The limitations of the blood, urine and biophysical methods for evaluation of nutritional status do not discredit them. Used appropriately each kind of method has value. Each has its place, each presents information on a different aspect of nutrition. The numerous articles in the literature describing studies by blood and urine methods attest their utility. For following the quick reflection of dietary habits in the body for secondary screening of persons without avitaminotic tissue changes, for specific metabolic studies, the blood or

urine technic is the method of election. Similarly, for studying disadaptation and night blindness the adaptometer is the proper instrument.

The methods which embody gross and biomicroscopic examination of specific tissues for characteristic morphologic changes—the eyes for avitaminosis A and riboflavinosis, the gums for avitaminosis C and the tongue for anacinarosis—meet most requirements for appraising nutritional status. Particularly they permit both the acute and chronic forms of tissue change in any stage and degree to be detected. True, if the tissue is normal it is possible that the blood values may be low. This situation however is the least frequent in the general population. Such a circumstance would be encountered most often in infants and preschool children. But the biomicroscopic system as a primary screen is so sensitive in detecting the very early or mild form that routine blood values as a secondary screen would add information in only a comparatively small number of instances.

There are still some gaps in the several systems for appraising nutrition. Despite the lack of a few tests there are now enough for application. Considering the rapid progress in this field, it is to be expected that before long the systems will be rounded out.

PREVALENCE OF MALNUTRITION

Obviously the recorded prevalence of malnutrition depends on the concept, criteria and means of recognizing it. In the past it has been judged by physical measurements or by presence of assorted gross signs, including those of the severe acute type of deficiency disease. Neither method has revealed any considerable prevalence of malnutrition. It is very misleading to rely on them for evidence on the amount of malnutrition. Simple inspection is not sufficiently sensitive to detect mild deficiency states, whether acute or chronic. Most of the chronic changes, even when severe, have not been recognized as specific characteristics of deficiency diseases. These conditions constitute the largest part of malnutrition.

Already the gross and biomicroscopic methods of examining tissue have yielded results indicating a high prevalence of deficiency states.¹⁴⁴ Even in high economic groups there are few people in absolutely perfect nutrition. Yet these results are not surprising. Very few persons have consistently followed throughout life a diet satisfactory in all essentials, escaped the many other causes contributing to a deficiency state or had complete recovery from any impairment of their nutrition. The older the person the more opportunity he has had for some dietary lapse or adverse influence. Then too the standard of perfection in the tissue is very exacting. And the biomicroscopic method is so sensitive that it is capable of detecting slight abnormalities. From all these considerations, the high prevalence of deficiency diseases is not unexpected.

Taken by and large most of the malnutrition is chronic, with or without mild acute, some of it is mild but much is rather severe.¹³⁹ This condition too is understandable. Often faulty diets persist for many years.

Some broad generalizations can be drawn about the several states in relation to factors affecting them. Like prevalence, the status of a deficiency disease is influenced by economic level, geographic region and age as well as by lesser environmental factors. Of these three it may be seen that the first two are indexes of the number, nature and degree of dietary deficiencies.

Age is again the time factor. In the lower economic groups, deficiency diseases tend to be more numerous, more severe and more advanced than in the higher economic groups. In geographic regions where a particular deficiency disease is endemic the severe acute form is common, in other regions it is rarely seen. In the latter it is mostly in the chronic form. At younger ages deficiency diseases are likely to be less prevalent and mostly in the mild acute or beginning chronic state, at older ages they are apt to be more frequent and largely in the chronic form.

These influences are not invariable, absolute or completely decisive. Economic level and geographic region are far from perfect correlates of deficient diets, and age does not initiate a deficiency disease. Nor are these influences of equal weight. Perhaps the most influential is economic level. But many persons in the higher economic groups do have severe deficiencies, while some in the lower miraculously escape. Only a small proportion of persons in an endemic region come down with a severe acute deficiency disease, almost all of these are in the low income group. As for the influence of age, adults may be normal, whereas children, particularly if they are from low income families, may exhibit a chronic process. We have seen numerous children from 8 to 11 years old and in low economic groups with chronic changes similar to those most frequent in the middle age group.

It is apparent that there is much malnutrition, most of it chronic in character. If we wish to be coldly scientific we can join the skeptic in asking: What of it? What is the justification for the expense and work in examining persons and treating the marginally malnourished? It is appropriate to raise the question whether the mild and chronic forms of malnutrition have any significance. Increasing evidence indicates that they have immediate and that they may also be found to have long range effects.

For one thing troublesome symptoms occurring in these mild and chronic forms of malnutrition and their disappearance under treatment may be noted objectively. In riboflavinosis, photophobia and lacrimation are frequently noted during the biomicroscopic examination.¹⁴⁴ Psychic manifestations have been observed in mild ariaminosis.¹⁴⁴ Doubtless, disturbing symptoms will be found in the mild stages of other deficiency diseases. Some are real handicaps. How much these symptoms dull the edge of health and lower performance in daily activities can now only be conjectured. In many instances, only after the symptoms have disappeared is their previous presence appreciated. Relief from such symptoms is no small benefit. The extent to which improvement is reflected in such activities as work remains to be demonstrated. In any event relief from symptoms may be regarded as one justification for the diagnosis and specific treatment of these mild and chronic states.

INFLUENCE ON MORBIDITY

Moreover, there are many strong intimations, short of proof, that malnutrition has a contributory or determining role in the occurrence of other diseases. This is the much debated question of the influence of nutritional status on morbidity. Up to now the lack of methods has made it difficult to supplant debate by demonstration on whether, or to what extent, impaired nutrition may play a part as a predisposing factor in

¹⁴⁴ William R. D. Mason, H. L. Wilder, R. M. and Smith, B. F. Observations on Induced Thiamine (Vitamin B₁) Deficiency in Man. Arch. Int. Med. 66: 785-799 (Oct.) 1940.

parasitic diseases, such as tuberculosis, and whether satisfactory nutrition may aid in building up natural resistance against such diseases. With the present availability of methods, this very promising and hopeful vista may be explored. However, we must not look for too much from nutrition, we must not expect it to confer absolute protection against disease. Other circumstances, of course, exert their influence. Rather, let us say that nutrition at most may be one factor affecting the probability of disease occurring. If that should be demonstrated it would be sufficiently important to warrant evaluation of nutritional status as a routine procedure.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary

ASCORBIC ACID, U. S. P. (See New and Nonofficial Remedies, 1942, p. 564)

The following dosage form has been accepted:

PITMAN-MOORE COMPANY, INDIANAPOLIS

Tablets Ascorbic Acid 50 mg

DIETHYLSTILBESTROL (See THE JOURNAL, June 20, 1942, p. 635)

The following dosage forms have been accepted:

GEORGE A. BREON & COMPANY, INC., KANSAS CITY, MO

Ampuls Diethylstilbestrol in Oil, 0.5 mg per cc 1 cc in vegetable oil

Ampuls Diethylstilbestrol in Oil, 1.0 mg per cc 1 cc in vegetable oil

Suppositories Diethylstilbestrol 0.5 mg

Tablets Diethylstilbestrol 0.2 mg, 0.5 mg and 1.0 mg

FREDERICK STEARNS & COMPANY, DETROIT

Tablets Diethylstilbestrol 0.1 mg, 0.5 mg and 1.0 mg

MENADIONE (See New and Nonofficial Remedies 1942, p. 584)

The following dosage forms have been accepted:

E. R. SQUIBB & SONS, NEW YORK

Thyloquinone (Crystals) bulk

Ampuls Thyloquinone in Oil (Intramuscular), 2 mg per cc 1 cc. Each cubic centimeter contains 2 mg of thyloquinone dissolved in corn oil.

Capsules Thyloquinone in Oil (Oral). Each brown gelatin capsule contains 1 mg of thyloquinone dissolved in corn oil.

Tablets Thyloquinone 1 mg

NICOTINIC ACID AMIDE (See New and Nonofficial Remedies, 1942, p. 562)

The following dosage form has been accepted:

THE UPJOHN COMPANY, KALAMAZOO, MICH

Sterile Solution Nicotinic Acid Amide 100 mg, 2 cc

RIBOFLAVIN (See New and Nonofficial Remedies, 1942, p. 559)

The following dosage forms have been accepted:

ABBOTT LABORATORIES, NORTH CHICAGO, ILL

Capsules Riboflavin 1 mg

Tablets Riboflavin 1 mg

SULFANILAMIDE (See New and Nonofficial Remedies, 1942, p. 142)

The following additional dosage form has been accepted:

E. R. SQUIBB & SONS, NEW BRUNSWICK, N. J.

Ampul Sulfanilamide (Crystals) 1 Gm

Council on Foods and Nutrition

ACCEPTED FOODS

THE FOLLOWING ADDITIONAL FOODS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO ACCEPTED FOODS.

FRANKLIN C. BING, Secretary

FATS AND OILS (See Accepted Foods, 1939, p. 30)

Wilson & Co. Inc. Chicago

WILSON'S CERTIFIED OLEOMARGARINE AND WILSON'S SAVORY OLEO MARGARINE FROM VEGETABLE SOURCES WITH VITAMIN A ADDED, an oleomargarine consisting of partially hardened cottonseed oil, cottonseed oil cultured skimmed milk salt emulsifier (manufactured by the firm consisting of diglyceride with minor amounts of monoglycerides, triglycerides and fatty acids) plus vitamin A concentrate in oil.

Analysis (submitted by manufacturer)—Moisture 15.1% fat 80.5% ash 3.11% protein 0.55% total carbohydrates 0.74% sodium chloride 3.0%

Calories—7.3 per gram 207 per ounce

Vitamins—The firm has supplied evidence that this product furnishes at least 9,000 U. S. P. units of vitamin A per pound.

Wilson & Co. Inc. Chicago

WILSON'S CERTIFIED OLEOMARGARINE AND WILSON'S SAVORY OLEO MARGARINE FROM ANIMAL SOURCES WITH VITAMIN A ADDED, an oleomargarine consisting of oleo oil, oleo stock, cottonseed oil, neutral lard salt cultured skimmed milk emulsifier (manufactured by the firm consisting of diglyceride with minor amounts of monoglycerides, triglycerides and fatty acids) plus vitamin A concentrate in oil.

Analysis (submitted by manufacturer)—Moisture 15.1% fat 80.5% ash 3.11% protein 0.55% total carbohydrates 0.74% sodium chloride 3.0%

Calories—7.3 per gram 207 per ounce

Vitamins—The firm has furnished evidence that the product supplies at least 9,000 U. S. P. units of vitamin A per pound.

FOODS FOR SPECIAL DIETETIC PURPOSES (See Accepted Foods, 1939, p. 295)

Chicago Dietetic Supply House, Inc. Chicago (distributor)

CELLU GREEN LIMA BEANS, canned green lima beans packed in water without added sugar or salt.

Analysis (submitted by distributor)—Moisture 77.4% sucrose 1.6% starch 9.55% crude fiber 1.17% undetermined carbohydrates etc. (by difference) 4.8% ether extract (crude fat) 0.19% protein (N \times 6.25) 4.67% ash 0.6%

Calories—0.85 per gram, 24 per ounce

FRUIT JUICES INCLUDING TOMATO JUICE (See Accepted Foods, 1939, p. 48)

Domino Canning Association, Bradenton, Fla.

DOMINO AND SUNSEAL BRANDS OF BLENDFO FLORIDA ORANGE AND GRAPEFRUIT JUICE (SUGAR ADDED), a mixture of Florida orange and grapefruit juices (sweetened).

Analysis (submitted by manufacturer)—Moisture 87.8% total solids 12.2% ash 0.5% fat (ether extract) 0.1% protein (N \times 6.25) 0.5% crude fiber 0.1% carbohydrates other than crude fiber but including citric acid (by difference) 11.0% sucrose 1.5% reducing sugar (as invert) 8.3% acid (as anhydrous citric) 1.1%

Calories—0.47 per gram 13.3 per ounce

Vitamins—Vitamin C (by titration with 2,6-dichlorophenolindophenol) 36.2 mg per hundred grams.

PREPARATIONS USED IN THE FEEDING OF INFANTS (See Accepted Foods, 1939, p. 156)

Gerber Products Company, Fremont, Mich.

GERBER'S JUNIOR FOODS—APPLE PRUNE TAPIOCA PUDDING, a canned cooked mixture of fresh apples, prunes, fresh whole milk, sugar, tapioca, cream (3.5%) and salt.

Analysis (submitted by manufacturer)—Moisture 73.2% ash 0.4% fat 1.0% protein (N \times 6.25) 0.2% crude fiber 0.8% carbohydrates (by difference) 24.3% calcium 0.012% phosphorus 0.012% iron 0.0014%

Calories—1.07 per gram 30.4 per ounce

Vitamins (Reports of assays furnished by firm 1942)—Vitamin A 240 I. U. per hundred grams, ascorbic acid 0.3 mg. per hundred grams.

Paley Sachs Food Company, Houston, Texas

MRS. PALEY'S BABY FOODS BRAND—STRAINED BEEF LIVER, a strained mixture of beef liver, water and salt.

Analysis (submitted by manufacturer)—Moisture 76.0% total solids 24.0% ash (mineral matter including salt) 1.4% fat 3.6% protein 14.2% total carbohydrate (by difference) 4.9% iron 0.005%, phosphorus 0.097% calcium 0.003%

Calories—1.0 per gram 29.3 per ounce

Vitamins—(Chemical assays submitted by firm)—Each hundred grams furnishes 6,500 international units of vitamin A and 0.035 mg. of thiamine.

SATURDAY FEBRUARY 27 1943

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

The thirty-ninth Annual Congress on Medical Education and Licensure sponsored by the Council on Medical Education and Hospitals of the American Medical Association was one of the most successful ever assembled. Indeed the results establish the necessity of the assembly in wartime. Elsewhere in this issue appears the contribution made to the congress by Pres. Edward C. Elliott, chief of the division of professional and technical employment and training in the War Manpower Commission, the statement of Brig. Gen. Joe A. Dalton, assistant chief of staff for personnel of the United States Army, describing plans for premedical and medical education as related to the United States Army, the contribution of Dr. Harold S. Diehl of the directing board of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians concerning medical education as related to the procurement and assignment of physicians, and finally a report by Col. George F. Lull, chief of the personnel division of the United States Army Medical Corps, on the utilization of physicians by the Army. Here are the answers to most of the questions which have been disturbing members of the medical profession in recent months.

President Elliott indicates the nature of the problems which confront the War Manpower Commission and emphasizes the fact that education as well as every other aspect of our lives must appreciate the inescapable requirements of global war. Brigadier General Dalton gives in detail an analysis of the premedical and medical programs, the methods by which students will be selected, the curriculums that they will follow, the emoluments that they will receive, the nature of the internship and many other facts about this procedure. Dr. Harold S. Diehl indicates some of the questions which continue to concern educators in medicine. His paper will no doubt bring these questions clearly before the authorities responsible for the ultimate functioning of the program

and enable them to act promptly in making every adjustment possible.

Colonel Lull has had one of the most difficult positions in the entire war effort, at least as far as medicine is concerned. The fact that the Army Medical Department had more than 35,000 medical officers on duty at the end of 1942 is an indication of the tremendous task that has been successfully accomplished. His citation of actual communications received from physicians in the service and his explanations of the duties which physicians in the armed forces must fulfill should answer many of the questions which continue to come to all those engaged in meeting the demands for personnel. The use of specialists in the armed forces, the formation of hospital units, the changing curriculum of the Medical Field Service School, the graduate courses now being developed, the use of women physicians and the provision of residents for hospitals are some of the problems which he analyzes and explains. It would be well if all could bear in mind one of his concluding statements:

When you hear from a disgruntled officer please evaluate his statements before you form an opinion of the entire medical service of the Army. Also remember that there are a lot of medical officers satisfied with their temporary jobs, and most of these do not write to you.

Among other problems discussed at this congress were graduate education and the war and medical licensure. The Surgeon General of the Navy, Rear Admiral Ross T. McIntire, gave a graphic account of the medical services in the South Pacific, and Surgeon General Thomas Parran provided a forecast of some of the medical problems of the postwar period. These additional contributions will be reflected in forthcoming issues of THE JOURNAL.

In his opening statement for the congress, Dr. Ray Lyman Wilbur, chairman of the Council on Medical Education and Hospitals, said in part:

We must all recognize the difficulty of holding our eager American youths at the risk of prolonged medical study when there are other and quicker ways of getting into the fight. So far we seem to have enough premedical students of quality to carry forward this year in our medical schools. The importance of medical training must be pointed out and the definite assignment by the Army and Navy of chosen men to medical schools must be put into effect. To run short of good doctors would be a calamity of the first magnitude. New methods of financing hospital care, new procedures under the auspices of the medical profession for medical care are constantly appearing. These with the changes in normal life due to the war are putting new responsibilities on every physician in the land. Modern science applied to human living has done more for our comfort and safety in the last fifty years than in all of the ages preceding. We must enter on our share in the war with the firm resolve to give all that medicine offers but with an even firmer resolve not to lose what we have won in the battle against disease and ignorance. Whatever the calls on us, we must see that medicine advances during the war and that it goes back at least to our highest level of achievement when the bombs stop dropping.

American medicine has performed remarkably in meeting the demands placed on it for the war effort. The officials of the government and officers of the armed

forces who have been charged with the task of providing for medical care have been sympathetic to the needs of medical education and of civilian medical practice. The accomplishment of the Council on Medical Education and Hospitals in providing at this congress statements from authoritative sources as to present plans and changes contemplated for the future in medical education and in medical practice merits the appreciation particularly of medical educators, since it stabilizes definitely a situation full in recent months of apprehensions and doubt.

IMMERSION BLAST INJURIES

The mechanism of the effects of blast in water is that of a single wave of pressure, the reflected wave from the sea bottom being of little importance. The pressure wave in water travels at the same speed as it does at first in air. However, the rate of fall of pressure is much slower than in air and varies directly with the distance, hence pressure effects will be expected over much greater distance. Williams¹ in his Hunterian Lecture, pointed out that the human body has roughly the same density as water. When the pressure wave impinges on the water there will be no reflection but the force will be transmitted through the tissues without displacement just as if the body were so much water. However, when the transmitted force encounters a cavity in the body containing air for example the lungs, the static wave of pressure will change into a wave of kinetic energy in the layers of tissue lining that cavity and a disruptive effect will occur. This apparently explains why the lungs and other gas filled cavities in the body are particularly susceptible to damage from the pressure wave, even though the body itself may not be deeply immersed.

Cameron and his associates² subjected goats, monkeys and dogs to the explosion of a 320 pound charge of trinitrotoluene suspended at 48 feet in water of 90 feet. The animals were buoyed up by inflated rubber tires round their necks and were secured to a line at various intervals. Studies of pathologic changes in animals thus exposed revealed severe pulmonary hemorrhages and interstitial emphysema, sometimes hemorrhage in the wall of the alimentary tract, occasionally hemorrhage in the epicardium, spleen, kidneys and ductless glands. Little damage was produced in the soft structures of the body wall and the bones.

Effects of immersion blast on man are also discussed in a symposium published in the January issue of the *United States Naval Medical Bulletin*. Observations on 35 patients treated at a naval hospital form the basis

for the report. According to Lieutenant Commander Palma and Lieutenant Uldall³ the severity of the symptoms depended on the distance of the men from the source of the explosion and on their own relative position in the water, whether horizontal or perpendicular, facing the blast or with their backs turned. From ten to forty-five minutes after the explosion the ones that were facing the blast or swimming in the prone position began to develop abdominal symptoms varying in degree from mild intermittent cramps to severe continuous abdominal pain. Several vomited and developed diarrhea. Many had hemoptysis lasting from twelve to twenty-four hours. The group that had their backs toward the blast or who were swimming in the supine position developed similar abdominal symptoms but to lesser degree, and their signs and symptoms were principally in the chest. Of the entire group only 14 had signs and symptoms of severe injury, the signs being chiefly those of shock and peritonitis. Physical signs in the chest were more often absent than present, but roentgenograms revealed in all but 1 case slight to moderate areas of increased density at one or both bases. Treatment was symptomatic and expectant, with the employment of sulfadiazine. In this group 6 recovered completely without an operation, 2 are recovering without an operation, 2 are recovering after surgical interventions and 4 died. Postmortem observations by Lieutenant Commander Ecklund⁴ in the 4 fatal cases revealed severe intra-abdominal lesions in each instance without any external evidence of injury. Sections from lungs showed extensive hemorrhage into the alveoli and rupture of the alveolar walls. Much the same observations were made by Cameron and his associates in their animal experiments. From these observations it appears that the principal seat of trauma in atmospheric blast is in the thoracic cavity, whereas the predominating injuries in immersion blast are abdominal.

Neurologic observations were, under the circumstances limited and unsatisfactory, and microscopic studies of the central nervous system were not made. Lieutenant Hamlin⁵ suggests in his discussion that a blast wave of sufficient magnitude may be transmitted to the spinal canal and thence to the cranial cavity, setting up a convection force in the cephalad direction through the spinal fluid and possibly the neuroaxis itself, which may be analogous to the phenomenon of cerebral acceleration that follows a blow to the head. Such a mechanism could damage the supporting vessels of the leptomeninges, giving rise to subarachnoid hemorrhage and neurologic symptoms.

More complete knowledge of the extent and mechanism of the lesions caused by immersion blast injuries

will be forthcoming from more thorough postmortem observations, preferably from immediately fatal cases, and from animal experiments. Such experimental studies are now in progress.

RESENSITIZATION OF SULFONAMIDE FAST BACTERIA

Encouraging new facts point toward successful therapeutic control of sulfonamide fast infections. Under certain test tube conditions or as a result of unsuccessful sulfonamide therapy numerous pathogenic bacteria acquire a tolerance or resistance to one or more of the sulfonamide compounds. They become able to multiply normally in the presence of the usual bacteriostatic concentration of these agents. Sulfonamide fast infections often do not yield to many times the usually successful therapeutic dose of sulfanilamide, sulfadiazine or sulfathiazole. Generally this acquired sulfonamide fastness is believed to be due to increased production by the organisms of sulfonamide inhibitors. This theory is in line with the fact¹ that bacterial extracts often contain a proliferative coenzyme ("P factor") which may be present in sufficient amounts to neutralize the bacteriostatic effects of sulfonamide compounds. Numerous known chemical substances also function as antisulfonamides, prominent among them being methionine and p-aminobenzoic acid.²

If increase in this P factor is the sole explanation of acquired sulfonamide fastness a logical method of overcoming this fastness would be to use some substance that would neutralize, inhibit or otherwise overcome the growth promoting action of this factor. Tsuchiya, Tenenberg and others³ of the Department of Bacteriology, University of Minnesota, found in early studies that the antisulfonamide action of methionine or of p-aminobenzoic acid can be overcome by the use of urea. In itself the inhibiting concentration of urea did not have demonstrable effect on the rate of bacterial growth. Tsuchiya and his colleagues⁴ have now tested whether or not similar concentrations of urea would have the same effect on sulfonamide resistant micro-organisms (P factor).

Three sulfonamide fast strains of *Staphylococcus aureus* were tested. One of these had been made sulfonamide fast in vitro and the two other strains were isolated from clinical cases which had failed to respond to prolonged sulfathiazole therapy. Using Gladstone's⁵ basal synthetic medium they found that addition of 60 mg of sodium sulfathiazole per hundred cubic centimeters did not have bacteriostatic effect on these three refractory strains. Inhibition of the normal

growth rate was not seen when from 1.25 to 1.75 per cent of urea was added to the synthetic medium. A combination of 60 mg of sodium sulfathiazole per hundred cubic centimeters and from 1.25 to 1.75 per cent of urea, however, often reduced the growth rate to one one-hundredth and at times to one one-thousandth of normal. Whatever may be the ultimate explanation of the nature of sulfonamide fastness, use of this urea-sulfonamide combination overcomes that fastness and renders the organisms resusceptible to sulfonamide bacteriostasis.

In evaluating their results it must be emphasized that thus far their "urea resensitization" has been demonstrated only for one sulfonamide compound, for one microbic species (*Staphylococcus aureus*) and only when it is grown in a relatively simple synthetic medium. There is no assurance of a similar synergic action with other sulfonamide compounds, other microbic species or on organisms suspended in serum, exudate or other body fluids. In vivo tests have not thus far been reported. Nevertheless the newly described combined action of urea and sulfathiazole is a discovery of basic clinical interest since it introduces a new concept in chemotherapy. The practical applications may in time be extended to numerous micro-organisms now considered refractory to sulfonamide drugs. The promised clinical report⁶ of the first practical applications of the new urea-sulfathiazole combination to human cases will be awaited with interest.

Current Comment

MEDICAL ACTIVITIES OF COMMONWEALTH FUND IN 1942

Current support of the Commonwealth Fund¹ in medical research is chiefly directed toward work which promises direct usefulness to war medicine, to investigations which offer significant contributions to the physiologic bases of medicine and to those which rest on long continued consecutive observation that cannot be interrupted without letting partly won facts slip out of reach. In medical education the special interest of the fund has been to help medical schools to make the most of the facilities at hand without gross enlargement of departmental budgets or capital outlay. Services on the borderline between psychiatry and pediatrics and the provision of opportunities for training in psychiatry continue to be the principal contributions of the fund toward the promotion and maintenance of mental health in this country. In addition, the fund cooperated in public health studies and has continued its rural hospital programs. The disbursements of the fund in these fields of medical interest in 1941-1942 exceeded \$1,200,000.

DURATION OF IMMUNITY FOLLOWING YELLOW FEVER VACCINATION

Since 1937 it has been possible to employ relatively safe vaccination against yellow fever by means of attenuated yellow fever virus unaccompanied by immune serum. This resulted from the development of a modified strain of virus (17D) which no longer produced either the visceral lesions of yellow fever or fatal encephalitis in rhesus monkeys. The duration of immunity following infection with 17D virus, however, previously had been studied on only a small scale and for periods not exceeding three years. Now Fox and Cabral¹ report large scale observations on the duration of immunity to yellow fever after vaccination with 17D virus over a four year period as determined by mouse protection tests. The persons included in their study all belonged to one or another of several well defined vaccination groups. Altogether 926 persons were studied, the total being composed of several large groups vaccinated at various intervals over this four year period. Recently collected serums and serums collected from the same persons soon after vaccination were examined for their protective action in mice and the results were compared. Some inconsistencies were observed. The evidence indicated that these variations were not due to previously unrecognized differences in the antigenicity of the 17D substrains concerned but rather to the different age compositions of the vaccination groups. Thus, only 4 (2 per cent) serums collected four years after vaccination from groups chiefly composed of adults failed to show some indication of protective action. In contrast, 36 (nearly 10 per cent) of serums collected two and three years after vaccination from groups largely composed of young persons were without protective power. Those serums which did not show protective action in the routine tests were reexamined by a more sensitive technic by which means detectable antibodies were revealed in 86 (61.8 per cent) of the 139 serums reexamined. These observations suggest that serologically demonstrable immunity against yellow fever induced by living 17D virus may completely disappear in some cases. Fox and Cabral also considered the significance of the low degrees of serologic immunity and showed that such low level immunity probably is sufficient to prevent reinfection with the 17D strain to which, in spite of its lack of virulence, man is highly susceptible. Finally, their observations on the duration of immunity following vaccination are of special significance with regard to the systematic prophylaxis of yellow fever. Thus vaccination of an adult population with a virus of established antigenicity results in the persistence of an immune state which is clearly satisfactory from the group standpoint for at least four years and probably longer. In children after vaccination the level of protective antibody does not rise as high as in adults and tends to fall more rapidly. As these investigators point out, whether or not the immunity of children conferred by vaccination is relatively

lower in degree and whether therefore the vaccination needs to be repeated after a shorter interval remains to be determined. Meanwhile this evidence of the reasonably persisting immunity from vaccination to yellow fever in adults is extremely welcome.

FITTING HANDICAPPED WORKERS TO JOBS

Industry, which in normal times has been loath to employ the handicapped worker, is now recognizing that many handicapped persons may be as efficient as those with full physical equipment and may be safer workers if they can be properly placed, trained and supervised. *Manpower Review*,¹ a publication of the War Manpower Commission, has recently considered the use of handicapped persons in industry as an aid to the war effort. The fitting of a handicapped person to his job demands that there be a breakdown of the requirements for all jobs in specific relationship to the exact procedures required, such as the degree of skill and strength demanded and working conditions which surround the job. Dovetailing with the detailed job analysis there must be an equally detailed analysis of the capability of the worker. When these frameworks of information have been established, adaptation of the handicapped person to the job becomes relatively simple. Adaptations of machinery may be made, such as shifting hand or foot levers so that they can be used by workmen with missing hands or feet. From Germany comes a report concerning measuring devices which use variations in tonal qualities of sound, such as a bell to enable blind workers to "read" the instrument. Persons unable to stand or walk much may be placed in sedentary jobs to which all material is brought and from which finished products are taken away by other workers or conveyors. A sample job analysis sheet indicates the demands for walking, standing, sitting, climbing, crawling, stooping, kneeling, lifting, pulling, pushing using one foot, using two feet, using one hand, using two hands, using fingers, seeing, talking, hearing and working speed for such industrial operations as operating presses, gage and weight machines, hardening furnaces, inspection jobs, molders, loaders and the like and also classifies these jobs according to such working conditions as outside, inside, hot, cold, humid, wet, dry, dusty, fumes, noisy, dirty. A tabulation of the estimated number of persons with various types of impairment by types of preemployment service needed indicated 901,000 with hearing impairment, 337,000 blind in one or both eyes, 1,849,000 with orthopedic impairment, 1,186,000 with hernia, 976,000 with hemorrhoids and more than 11,000,000 with chronic diseases. This list was based on an estimate by the United States Public Health Service. The latent manpower in these handicapped workers can be significant in the war effort. The physician, particularly the industrial surgeon, management and labor can cooperate in the constructive utilization of this vast potential reserve.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association announcements by the Surgeon Generals of the Army, Navy and Public Health Service and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY

THE TREATMENT OF BURNS

Circular Letter No. 15 of the Office of the Surgeon General is concerned with the treatment of burns. It was issued on January 11 to all medical officers of the United States Army. The suggestions which follow are therefore recommended as routine in the army medical service.

1 *General*—Burns as discussed in this paragraph include all cases with damage of the skin and underlying tissues due to heat, chemicals or electricity.

2 *Fundamentals of Treatment*—(a) The prevention and control of shock is the primary consideration in the management of every burn.

(b) Proper prophylactic measures against pyogenic infection, tetanus and gas gangrene should be taken. Satisfactory end results that is, minimal scar formation largely depend on the avoidance of pyogenic infection; the moist surfaces of burns provide ideal conditions for bacterial growth and it is therefore of paramount importance to employ, if possible, strict aseptic technique in operating on and dressing burns.

(c) Measures should be taken to relieve pain.

3 *Treatment*—(a) *General* (1) Proper steps for the prevention or treatment of shock should be instituted. In the presence of extensive burns quantities of plasma up to 12 units may be required during the first twenty-four hours. It is available concentrated normal human serum albumin in appropriate amounts may be used likewise. Transfusion of fresh whole blood is often needed to combat the rapidly developing severe anemia which follows extensive burns when anemia exists whole blood transfusion is particularly indicated as a preliminary to skin grafting. Parenteral fluid replacement other than that attained by means of plasma or whole blood transfusion should be accomplished by means of 5 per cent dextrose in sterile distilled water. The intravenous administration of sodium chloride solution should be reserved for those burn cases in which mineral depletion is pronounced as when great loss of electrolytes occurs as a result of persistent vomiting.

(2) In all cases of moderate to severe burns prophylactic chemotherapy should be administered. Sulfadiazine is the drug of choice (sulfanilamide may be substituted) with an initial dose of 4 Gm (60 grains). Subsequent doses of sulfadiazine should be given only under the direction of a medical officer. It should be kept in mind that although sulfonamide therapy may serve to prevent infection great care must be exercised in employing such therapy in burn cases. The extensive fluid loss and possible kidney damage so common in burn cases increase the danger of renal complications from sulfonamide therapy. Maintenance doses of sulfadiazine should be given in 0.5 Gm (7½ grains) doses every four hours until such time as adequate kidney function can be demonstrated under which circumstance the dosage may be increased to 1 Gm (15 grains) every four hours.

(3) Prophylaxis against tetanus is indicated for all patients with second or third degree burns.

(4) A prophylactic dose of gas bacillus antitoxin may be given at the discretion of the medical officer.

(5) Pain should be relieved by adequate doses of morphine. Pain resulting from an extensive burn can ordinarily be relieved by a dose of ½ gram of morphine. In the presence of pronounced anoxia large doses of morphine are dangerous and under such circumstances the dose should not exceed ¼ gram.

(b) *First Aid or Emergency Treatment of the Burned Area*

(1) The burned surface should be covered with a liberal amount of boric acid ointment or, if this is not available, with petrolatum. The burn should then be covered with strips of a sterile fine mesh gauze (44 mesh gauze bandage is satisfactory). Over this should be added a smooth thick layer of sterile gauze dressing (large or small first aid dressings are especially suitable for this purpose). Finally a gauze or muslin bandage should be firmly applied over the dressings.

(2) Contamination of burned surfaces by organisms from the nose and throat is responsible for most of the more serious infections which subsequently develop. Therefore, to minimize contamination from this source, masking should be practiced by the surgeon and assistants. If masks are not available, mouths should be kept closed.

(3) The prompt administration of plasma, when feasible, constitutes an important element in the emergency treatment of burns.

(c) *Definitive Treatment of the Burned Area* The burned area should be treated as follows: standard operating room technique if possible, being employed with the patient, as well as all attendants fully masked.

(1) Ether, benzene, lard or other detergents should be used to remove grease, if present. The burned area and then separately the surrounding skin are to be carefully cleansed, using neutral soap and water. Green soap should not be used. Avoid the use of brushes in the cleansing of the burn.

(2) All blisters and loose shreds of epidermis are carefully removed, and this material is saved for bacteriologic study, if feasible. Skin that gives evidence of irreparable damage through its full thickness should be excised (evidence of irreparable damage to deeper layers of skin may not be apparent for several days, and excision in such cases should be done as a secondary procedure). The resulting wound should be handled like any other open surgical wound, primary grafting of skin being carried out if conditions permit. For painful surgical procedures or dressings general anesthesia, preferably obtained by intravenous injection, should be employed.

(3) Burns of surfaces of any portion of the body may be treated with boric acid ointment. After thorough surgical cleansing, the burned area should be covered with a generous application of boric acid ointment. Strips of a fine mesh sterile gauze (44 mesh gauze bandage is satisfactory) should be applied. Over this should be added a smooth thick layer of sterile dressing, this may consist of gauze absorbent cotton, cotton waste or cellulose. The dressings should be held in place by an evenly and firmly applied bandage, stockinet or some form of elastic bandage is more effective than the ordinary roller bandage. The dressing should not be disturbed for ten days unless complications develop. Firm pressure is especially important in the case of burns of the hands and face. Immobilization of the part by splinting should be effected when feasible.

(4) As an alternate method of definitive treatment, burns of all surfaces except those of the hands, face, genitalia and those involving the circumference of an extremity may be treated with tannic acid and silver nitrate. This method however, should not be employed in the instance of burns which are grossly contaminated or in which twelve or more hours have elapsed since the receipt of the burn. A freshly prepared 10 per cent aqueous solution of tannic acid is sprayed over the burned area. This

is followed immediately by spraying the area with a mixture of equal parts of 10 per cent tannic acid and 10 per cent silver nitrate solutions. This mixture should then be sprayed on the burn every half hour until a satisfactory eschar has been formed. Care should be taken to avoid spraying normal skin about the wound. While drying, the burned area may be kept exposed to the air in a heated cradle. After the eschar is dry, it may be covered by a dry sterile dressing. In the absence of infection, the eschar should be allowed to separate spontaneously. If infection develops, the eschar must be removed from the entire infected area, and the latter should then be treated like any other infected wound with the employment of appropriate systemic and local therapy.

(5) Isotonic solution of sodium chloride has been found useful in the treatment of burns involving the face, hands and especially fingers, the flexures and the perineum. It may also be used for the treatment of surface infections following the removal of eschars produced by tannic acid or other agents. Saline solution may be employed in the form of packs or baths.

SILVER STAR AWARDED TO LIEUTENANT HAVLIK

Lieut. Aloysius J. Havlik, M. C., U. S. Naval Reserve, formerly a practicing physician at Tama, Iowa, was awarded the Silver Star for distinguished service as medical officer aboard a destroyer during the battle north of Santa Cruz Islands on Oct. 26, 1942. Lieutenant Havlik's wife, who is now at Audubon, Iowa, writes that her husband has been on destroyer service since May 8, 1942. The award was made February 6 by Admiral W. F. Halsey. The citation was as follows:

In the name of the President of the United States, the Commander of the South Pacific Area and South Pacific Force takes pleasure in presenting the Silver Star Medal to Lieutenant Aloysius J. Havlik, Medical Corps, U. S. N. R., "For distinguished service in the line of his profession as Medical Officer aboard a destroyer in action against the enemy during the battle to the northward of Santa Cruz Islands on Oct. 26, 1942. While his ship was being subjected to a determined enemy aerial attack, Lieutenant Havlik with utter disregard for his own personal safety coolly and efficiently sought out and cared for the wounded wherever they might be. His actions were in keeping with the highest traditions of the Naval Service."

SCHOOL OF MILITARY GOVERNMENT AT CHARLOTTESVILLE

The Army opened a school of military government at the University of Virginia at Charlottesville, May 11, 1942, where officers are trained for future detail with military government and liaison and to assist commanders in foreign fields in their relations with the civilian population. The commandant of the school is Brig. Gen. Cornelius W. Wickersham, a son of the former Attorney General and a graduate of Harvard College of Law School, who practiced law in New York City. General Wickersham served on the Mexican border and during the first world war in France, where he was awarded the Distinguished Service Medal and the French Legion of Honor, and later as chief of staff of the seventy-seventh division organized reserve.

The University of Virginia offered its facilities and the privileges of its library. The school uses lecture rooms in the law school building as well as a building for administration. The first four months' course of study was attended by sixty student officers and the second course by one hundred and fifty student officers, among whom were fifteen medical and sanitary corps officers. Among other members of the faculty of the School of Military Government are Col. Frank H. Hastings, C. A. C., assistant commandant, Major Hardy C. Dillard, A. U. S., director of instruction, and Profs. Arnold Wolfers of Yale, Henry Rowell of Johns Hopkins and Hugh Borton of Columbia, who will assist the permanent faculty. Special lectures have been given by two former judge advocates of the Army, Major Generals Blanton Winship and E. A. Kreger, and by Profs. Charles C. Hyde and Phillip C. Jessup of Colum-

bia, Max Lerner of Williams, W. Y. Elliott of Harvard, N. J. Sytkman of Yale, President Isaiah Bowman of Johns Hopkins and Dr. David A. Lockmiller of Duke. Courses are given in international law, public administration, army organization, military government, liaison functions and duties, and study of the politico-military backgrounds of enemy countries. Another class reported for training on January 9.

COURSES TO ORIENT MEDICAL OFFICERS FOR THE AIR FORCES

A course is given at the Army Air Forces Officer Training School in Miami Beach, Fla., for the purpose of orienting medical department officers coming from civilian life and to prepare them for duty for the army air forces. This course is similar to the regular officer training school courses given for the air forces and yet varies in some respects to meet the special needs of medical department personnel. The military training given to the medical department officers is the same as that given by the army air forces officers. The academic training is given in subjects peculiar to the medical department. The medical department student officers have composed about one third of the student body of the officer training school since last November and they have frequently taken the military and academic honors. One of the first ten honor students in class 1942-R was Capt. Carl M. Binnig of Westfield, Mass. The training of the medical officers at the army air forces training school, Miami Beach, is under the supervision of Major Sidney Davidson, M. C.

COLONEL GILLESPIE AWARDED DISTIN- GUISHED SERVICE MEDAL

The War Department has announced that Col. James O. Gillespie, M. C., U. S. Army, who was chief of the medical service at the Sternberg General Hospital in Manila at the outbreak of the war, has been awarded the Distinguished Service Medal for developing hospitals on Bataan Peninsula with only "extremely limited personnel and equipment." Colonel Gillespie is said now to be a prisoner of war, held by the Japanese at Camp Tarlac, formerly Camp O'Donnell, some 65 miles north of Manila. In the absence of her husband, the medal was presented to Mrs. Gillespie by the commanding general of the ninth service command. Colonel Gillespie is a native of North Dakota, an honor graduate of the University of Minnesota Medical School and a graduate of the Army Medical School, Washington, D. C. and of the Medical Field Service School at Carlisle Barracks, Pa.

AVIATION PHYSIOLOGISTS

A class of aviation physiologists graduated at the School of Aviation Medicine in Texas on January 23. The course, which is of several weeks' duration, treats of the effects of lowered barometric pressure, the effect of flight on man, the operation of low pressure chambers, the theory and practical use of oxygen equipment and the conduct of high altitude indoctrination and classification. Among the graduates were the following medical officers: First Lieuts. Kyle T. DeYarman, Morning Sun, Iowa; Bernard B. Grossman, Corpus Christie, Texas; Arch C. Koontz, Woodboro, Texas; John Meyers, Worcester, Mass.; Louis Miller, Cleveland; Samuel Schwartzberg, San Antonio, Texas; Capt. Vernon C. Kenney, Chagrin Falls, Ohio; and Clarence R. Schmidt, Seattle and Major James H. Hammond, Tulsa, Okla.

ARMY AIR FORCE MEDICAL DEPART- MENT OFFICERS GRADUATE

Another class of student officers at the Officer Training School for Army Air Force Medical Department Officers graduated on January 9 at Miami Beach, Fla. Medical department officers comprised about one third of the graduating class of more than six hundred officers. Four medical officers were among those who graduated with distinction. The top man of the entire class was First Lieut. Milton Elkin, Boston, and among the ten highest in the class were First Lieuts. Milton L. Berg, Perry; J. Culver and John Homans, Jr., all of Boston.

NAVY

RETIRED NAVAL MEDICAL
OFFICER COMMENDED

The Navy Department announced on January 24 the award of a letter of commendation to Lieut Comdr Marvin M. Gould M. C., U. S. Navy, retired, for his services in caring for victims of the Cocoanut Grove fire in Boston on Nov. 28, 1942. The citation reads:

The Department has been informed that on the occasion of the fire in the Cocoanut Grove, Boston, Mass., on November 28, 1942, you assumed charge and directed the work of naval medical personnel, not only at the scene of the fire, but also at hospitals and mortuary. Under your direction, medical assistance was given to civilians and to members of all branches of the armed forces with the result that pain and suffering were relieved quickly and effectively and the lives of many saved. For the skill, endurance, tact and devotion to duty displayed on this occasion, you are hereby commended.

Dr. Gould was retired in 1939 and ordered back to active duty in 1940. He graduated from the University of California Medical School in 1916 and is at present assigned to the Boston Navy Yard.

DR. W. B. MacCRACKEN AWARDED
NAVY CROSS

Dr. William B. MacCracken II of Berkeley, Calif., was recently awarded the Navy Cross by the Commander in Chief of the Pacific Fleet, Admiral Chester W. Nimitz, in the name of the President of the United States. The citation reads as follows:

'For extraordinary heroism and devotion to duty in actual conflict with the enemy as Senior Medical Officer of the landing force of the Marine Raider expedition against the enemy-held island of Makin on Aug. 17-18, 1942. When the first air attack was made, he personally carried many of the wounded to positions of greater safety. His utter lack of concern for personal safety not only enabled him to give early and effective aid to the wounded but served as an inspiration to all. During the first attempt at evacuation his boat overturned, endangering the life of a seriously wounded private, who was unable to help himself. He saved the life of this man by keeping his head above water and swimming ashore with him. After returning to the ship he performed six major operations under the most difficult conditions and succeeded in bringing all his cases back to the base in excellent condition. His courage and devotion to duty are in keeping with the highest traditions of the naval service.'

CIVILIAN DEFENSE

NEW AIR RAID WARNING
SIGNAL SYSTEM

As a result of studies made by the War Department in the Office of Civilian Defense, a new system of air raid signals became effective February 17 for the Eastern Defense Command which includes Maine, Vermont, New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Delaware, Pennsylvania, Maryland, Virginia, North Carolina, South Carolina, Georgia and Florida east of the Apalachicola River. The remainder of the country is not affected, however, the Office of Civilian Defense, Washington, D. C., recommends that the states between the Eastern Defense Command and the Western Defense Command adopt the new regulations of the Eastern military area.

The principal features of these new regulations are: 1. A preliminary Blue signal consisting of a long steady blast on an air raid siren, horn or whistle, lasting about two minutes and meaning 'Probability of enemy air raid. Enemy planes appear to be headed in your direction. Get ready.' 2. A Red air raid signal consisting of a series of short blasts on air raid horns or whistles or the warbling notes of the siren meaning

THE NAVY'S WEEKLY NEWS

The Office of the Surgeon General of the Navy began on February 8 the publication of the *Weekly News*, which is designed to be a medium of value to the personnel of the Bureau of Medicine and Surgery of the Navy, and to enhance the functional activity of the bureau by keeping the various divisions and sections abreast of changes, proposals and advances. The effort of all personnel of the Bureau of Medicine and Surgery in making the *Weekly News* the unifying link of the various sections and divisions of the bureau is much desired. The first issue contains a list of the speeches and conferences to be given or attended by members of the bureau, information concerning appointments in the bureau, visitors and the increase in hospital facilities expected during the coming year.

HOSPITAL CORPS WAVES

The Surgeon General of the Navy has requested from the Bureau of Naval Personnel the procurement of 5,800 Hospital Corps Waves for assignment to continental activities in order to make available for sea duty hospital corpsmen who are now assigned to shore duty. These Wave members of the Navy Hospital Corps are enlisted as apprentice seamen V-10, U. S. Naval Reserve, and then undergo a routine period of indoctrination at Wave schools following which they are advanced to hospital apprentice ratings and transferred to the Naval Medical Center, Bethesda, Md., to the Naval Hospital, San Diego, Calif., or to other naval hospitals for further indoctrination and duty. The first groups of Wave technicians have arrived at San Diego and Bethesda.

In addition thirty-eight Yeomen Waves have been requested for assignment to the Bureau of Medicine and Surgery as replacements of hospital corpsmen and are expected to arrive at the bureau about March 15.

NAVY HOSPITAL FACILITIES

Existing naval hospitals in the United States and the current construction program will provide about 40,000 beds by June 30. The expansion planned for the year 1944 is 20,000 additional beds in hospitals by acquisition of existing structures such as hotels, by expansion of present hospital facilities and possibly by construction of new naval hospitals at various places. The neuropsychiatric section has recommended additional hospitals for the care and treatment of casualties returning from combat areas and ships, suffering from nervous manifestations in conjunction with fatigue and exhaustive states, according to the *Bureau of Medicine and Surgery Weekly News*.

Enemy planes are practically overhead" 3. A "Blue" signal will always follow each "Red" signal after the immediate danger has passed. The community is thus prepared to return to the "Red" without delay if the enemy raiders return. 4. No audible "All Clear" signal is prescribed. The "All Clear" will be indicated by turning on those street lights which have been off during the "Blue," by public radio announcements and telephone, or other communications with warden posts, and by local police. Further details of this new air raid warning signal system will be found in Operations Letter No. 107 of the Office of Civilian Defense, issued January 28.

EMERGENCY MEDICAL SERVICE
IN PERRY COUNTY

The Perry County (Ky.) Medical Society, cooperating with the local civilian defense council, has appointed Dr. L. C. Coleman, medical auxiliary officer, to supervise the emergency medical organization modeled after the plan suggested by the Office of Civilian Defense and comprising eighteen casualty stations, four-

teen of which are in rural parts of the county and four in the cities of Hazard and Lott. The purpose of the casualty stations is to receive the injured in case of air raid or flood, epidemic, fire or explosion, to treat the less seriously injured and to send to hospitals the more seriously injured. The plan further provides for other local physicians and nurses to report at designated stations in case of a serious emergency.

COURSE ON MEDICAL ASPECTS OF CHEMICAL WARFARE

The Office of Civilian Defense sponsored at Northwestern University Medical School, Chicago, January 14-16, an instructors' course for civilian physicians on the medical aspects of chemical warfare. Among the many demonstrations and classes was a gas mask drill and a gas chamber exercise conducted at Navy Pier by Capt N H Fritz of the chemical warfare service, sixth service command, and by Lieut John Pabst, U S Navy, respectively. Among the other instructors were officers

from Great Lakes Naval Station, the local office of civilian defense and from Johns Hopkins University School of Medicine, the University of Chicago and Northwestern University.

NURSING AND THE EMERGENCY MEDICAL SERVICE

The Medical Division of the Office of Civilian Defense is organized along the following functional lines: field casualty service, hospital care, nurse service, blood plasma production and distribution, rescue-first aid, gas defense, sanitary engineering, plant protection and scientific research. The Medical Division recently issued Bulletin No 6 which summarizes the work of the nursing service and of the emergency medical service and that of volunteers in health, medical care and nursing. This bulletin contains also official information concerning the U S Citizens Defense Corps, the U S Citizens Service Corps, the Civilian Defense Auxiliary Group, home water supply precautions, protection against injury from war gases, and insignia, identification and dress for nurses.

MISCELLANEOUS

PHYSICAL THERAPY EQUIPMENT UNDER STRICT CONTROL

Physical therapy equipment was placed under strict control, February 16, by the Director General for Operations with the issuance of an order limiting its production and distribution. The order prohibits the manufacture of all types of physical therapy equipment except surgical diathermy units, electric bakers, fever cabinets and other items which it specifically names. The prohibition, however, does not extend to approved purchase orders for the armed services or for Lend-Lease purposes. All manufacturers of physical therapy equipment must file monthly production and shipping schedules on WPB Form PD-774. While the items specifically named are not placed under production limitations, their sale or delivery is subject to strict control and permissible only on purchase orders for the armed services, Lend-Lease, Board of Economic Warfare, hospitals or medical departments of industrial concerns. Items that cannot be manufactured hereafter may be distributed without restriction until present stocks are exhausted. Examples of items of this kind are vibrators, sun lamps and other heat applicators widely distributed through drugstores and similar retail outlets.

The order affects all distributors or dealers handling those items whose delivery is restricted and about twelve large and twenty-five smaller manufacturers of all types of equipment.

EYE GLASSES AND PRICE REGULATION

Definitions of the extent to which maximum prices are established on services rendered in connection with the examination of eyes for glasses were issued February 13 by the Office of Price Administration, which laid down these rules as controlling:

1 All sales of eye glasses and spectacles are subject to the General Maximum Price Regulation, under which ceilings are the highest prices prevailing in March 1942.

2 The charges to a person for services involving the examination and refraction of eyes are not subject to the General Maximum Price Regulation if the seller is not selling corrective eye glasses or spectacles to that person, either as part of the same transaction or as part of the same general course of dealing.

3 If a seller is rendering to any person services involving the examination and refraction of eyes and he is also selling corrective eye glasses or spectacles to that person either as part of the same transaction or as part of the same general course of dealing, the following rules apply:

(a) If the seller makes a single charge for the sale of both the glasses and the services, the joint sale is subject to the General Maximum Price Regulation.

(b) If the seller makes a separate charge for the sale of the glasses and a separate charge for the sale of the services and during March 1942 he customarily made separate charges, then the charge for the services is not subject to the General Maxi-

mum Price Regulation. The sale of the glasses, however, is subject to the General Maximum Price Regulation.

(c) If the seller makes a separate charge for the sale of the glasses and a separate charge for the sale of the services, but in March 1942 he did not customarily make separate charges, and made a single charge for the services and the glasses, then the sum of the charge for the examination and refraction of eyes plus the charge for the sale of the glasses is subject to the General Maximum Price Regulation and shall not exceed the highest charge made in March 1942 for the same combination of services and glasses. In order to maintain the correct maximum prices on the sale of the eye glasses, the sale of the glasses and the sale of the services shall be treated as a joint sale of the glasses and the services and are subject to the General Maximum Price Regulation.

These rules are embodied in Amendment No 110 to Supplementary Regulation No 14 of the General Maximum Price Regulation, which is effective February 19, 1943.

In view of these rules, OPA stated that a finding on the question of whether these services are professional as the term is used in section 302 (c) of the Emergency Price Control Act is unnecessary.

MOBILE HOSPITAL UNIT CITED

Adm Chester W Nimitz, Commander in Chief of the U S Pacific Fleet, has awarded a citation for distinguished service at the time of the attack on Pearl Harbor, Dec 7, 1941 to Mobile Hospital Unit No 2 the commanding officer of which when the raid occurred was Capt John H Chambers, M C whose home is in Philadelphia, and the executive officer Capt John M McCants, M C, Fernandina, Fla. This mobile hospital unit (No 2) had been shipped to Hawaii shortly before the Japanese attack on Pearl Harbor and although construction of the unit had not been completed, its staff promptly undertook the care of those wounded in the raid. Operating skilfully and otherwise working for many hours the doctors, nurses and hospital corpsmen attached to the Mobile Hospital Unit No 2 rendered full medical care to the casualties.

ARMY-NAVY PRODUCTION AWARDS

Merck & Company, Inc. manufacturing chemists at Rahway, N J, were awarded the Army-Navy Production Award, February 9, comprising a flag to be flown above the plant and a lapel pin symbolic of distinguished service to America for every employee in the plant. Among those present at the ceremonies were the Hon Charles Edison, governor of New Jersey, the Hon David Armstrong mavor of Rahway, Lowell Thomas as master of ceremonies, Major Gen James C Magee, Surgeon General, U S Army, Rear Admiral Luther Sheldon Jr, U S Navy, George W Merck, president of the company, and George E Lennox, president of the employees' organization. The printed program also contained a list of hundreds of Merck

employees who are now serving in the armed forces of the United States and the names of two who have been killed in action

The employees of Burroughs Wellcome & Co., manufacturing chemists in Tuckahoe N. Y. have been presented with the Army-Navy E Award. This worldwide organization produces immense quantities of medicinal preparations and first aid equipment for use of the allies.

The employees of the General Electric X-Ray Corporation were presented with the Army-Navy E Production Award February 16 at ceremonies held at the Crane Technical High School 2245 West Jackson Boulevard Chicago.

LEND-LEASE AID FOR FRENCH NORTH AFRICA

President Roosevelt on Nov. 13, 1942, directed that lend-lease aid be extended to people of French North Africa and the first step was the purchase of about \$5,000,000 worth of civilian goods for North Africa. Many times that amount will be procured in coming months to be sent as shipping space becomes available. Among the items to be purchased under this program for North Africa are medical and hospital supplies, sugar, powdered and evaporated milk and cheese, cotton textiles, ready-made new and used clothing and shoes, copper sulfate to increase the production of vegetables and fruits for consumption by American troops as well as the inhabitants, coal for transportation and kerosene for lighting. It has since been announced that Ethiopia also will be included in the lend-lease program.

Back of the lend-lease program is the idea of pooling the resources of the United Nations. South and West Africa are doing much to supply fruits and vegetables to American soldiers in those areas. This system of mutual aid means the building up of a modern transportation system which should be of lasting benefit to the peoples of the Dark Continent.

AMERICAN-RUSSIAN COMMITTEE

Dr. Michael Michailovsky, treasurer of the American Russian Committee for Medical Aid to the U. S. S. R., Inc., 55 West 42d Street, New York City, has submitted a financial report to the committee for the period from Aug. 18, 1941 to Jan. 8, 1943, which shows total cash receipts of \$185,091.33 and total disbursements of \$179,619.26, leaving cash in the bank on January 8 of \$5,472.07. Of the total disbursements, \$164,075 was turned over to Russian War Relief, Inc., for purchase and shipment to the U. S. S. R. of medical supplies and surgical instruments. In addition, there was \$12,496.47 of miscellaneous receipts, making the grand total \$197,587.80. Of the total disbursements by the committee, less than 3 per cent, or \$5,750.43, was expended for administrative purposes. The president of the American Russian Committee for Medical Aid to U. S. S. R., Inc. is Prince Vladimir V. Koudasheff and the secretary is Margarita Konenkova.

PSYCHIATRIST AT WAAC CENTER

Dr. Nita M. Arnold, former Chicago psychiatrist, is a contract surgeon with the rank of first lieutenant at the First WAAC Training Center, Fort Des Moines, Iowa. She is under contract with the Surgeon General of the Army. Dr. Arnold was born in Buenos Aires, Argentina, in 1898 and graduated at the Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, in 1930.

MEDICAL MEETING AT TRUAX FIELD

The staff of the Station Hospital at Truax Field, Madison, Wis., held a meeting on February 9 to which members of the Dane County Medical Society and the staff of the Wisconsin General Hospital were invited. The scientific program presented was as follows:

Major Dorris F. Rudnick: Control of Venereal Disease in the Army.
Major Herbert D. Glick: Physical Requirements of the Flier.
Major John Chornyak: Psychiatric Problems Seen in the Army.
Major Charles S. Higley: Primary Atypical Pneumonia in the Army.
Major Bernard B. Larsen: Common Surgical Conditions Seen in the Army.

LIEUT. RUTH STRAUB AWARDED LEGION OF MERIT

Lieut. Ruth M. Straub of the Army Nurse Corps left her home in Greendale, Wis., in 1939 to be commissioned at Fort Sheridan, Ill., and almost immediately was sent to Manila. On Dec. 26, 1941, Lieutenant Straub was sent along with hundreds of patients in a boat to Corregidor, in February she was ordered to Bataan to work in a field hospital in the jungle, and which all nurses were ordered to evacuate in April. Their small boat made the trip to Corregidor just ahead of the Japanese in May. Lieutenant Straub with eleven other army nurses and one navy nurse then boarded a submarine and were returned to the United States by way of Australia. Lieutenant Straub has now been assigned to the Marana Base Flying School near Tucson, Ariz., after having been awarded the Legion of Merit at Washington, D. C.

PUBLIC HEALTH UNDER HITLER

According to Transocean of Dec. 14, 1942, an announcement has been made by well-informed scientific quarters in Berlin that the new German methods of combating typhus fever have proved so successful that the mortality rate has now been reduced to about 1 per cent.

New details of the German measures to combat typhus fever were announced at the opening of the great Typhus Research Institute of the German supreme command in Cracow, which has succeeded in producing bacteria in time to be used for prophylactic vaccination. These bacteria, which are kept alive in cans, are now being mass-produced by a new technical process and dispatched to the German and allied troops fighting in the East. Hospitals and doctors have thus become entirely independent of fresh bacteria, as they can now use the canned bacteria.

A new method of diagnosing typhus fever has also been worked out. While it used to be necessary to take a sample of blood from the arm of a suspected patient, it is now only necessary to take a pinprick drop of blood from the lobe of the ear. The particular advantage of the new method is that it can be employed rapidly and by any untrained person or by the patient himself.

DAB of Dec. 9, 1942, states that on all fronts in the occupied territories and in the homeland, well-known doctors of all branches of medicine are assisting the medical officers serving with the forces and in the military hospitals in an advisory capacity. They guarantee that diagnosis and treatment for the German soldier always conform to the most up-to-date standards of medical knowledge and research. To discharge their duties properly, these consultant physicians must have opportunities to exchange their experiences gathered under wartime conditions. For this purpose, a large number of consultant physicians of all branches of medicine and from all theaters of war recently met at a conference at the Academy for Military Medicine in Berlin. The meeting was called by General Oberstabsarzt Prof. Dr. Handlauer, the head of the medical services of the armed forces. It was the first conference at which all the three services were represented as well as the Waffen-SS, the police and the organizations attached to the armed forces such as the Reich Labor Service and the Organization Todt. Scientists of repute from all these formations took part in the meeting. Among the people who followed the lectures and discussion with interest were the teacher's general commissioner for health and medical services, Obersarzt Prof. Dr. Brandt, Secretary of State Dr. Conti, and the medical inspectors of the three services, the Waffen-SS, the police and the organizations attached to the forces. All possible problems of medical care for the soldiers were thoroughly discussed during the conference, and every possible attention was paid to the problems of the new winter campaign. Just as much care was devoted to prophylactic measures and to the preservation of health as to the treatment of injuries which cannot always be avoided. New knowledge was made available to the medical officers with the troops at the front and the specialists in the military hospitals so as to enable them to discharge their tasks as comrades of the fighting German soldier. The conference confirmed the feeling of certainty of success and of the victory of the German spirit which by its discoveries and achievements is making constant progress possible in the art of medicine too.

ORGANIZATION SECTION

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—S 180 has been reported to the Senate with recommendation that it pass, a bill to provide vocational rehabilitation education, training and other services to persons disabled while members of the armed forces, or disabled in war industries or otherwise and to render such persons fit for service in war industries, agriculture or other useful civilian industry. H R 801 has been favorably reported to the House, a bill to provide for the rehabilitation of disabled veterans of the present war.

Bills Introduced—S 607, introduced by Senator Kilgore, West Virginia for himself and Senator Pepper, Florida, Senator Murry Montana, Senator Bill, Minnesota, Senator Capper, Kansas, Senator Green, Rhode Island, Senator Johnson, Colorado, Senator LaFollette, Wisconsin, and Senator Thomas, Utah, proposes to establish an Office of War Mobilization to inventory and mobilize all the economic resources of the United States, including manpower, facilities, materials, technical and scientific knowledge, and natural resources for maximum use in the provision of military and essential civilian needs. An Office of Scientific and Technical Mobilization would be created to effect the full and immediate mobilization of scientific knowledge, techniques and personnel, for the prosecution of war and for making adjustments necessitated by war conditions. S 692, introduced by Senator Downey, California, provides compensation for personnel sustaining disease or injury while performing civilian defense duties. S 699, introduced by Senator Bilbo, Mississippi, provides pensions to peacetime veterans of the Regular Army, Navy, Marine Corps and Coast Guard suffering from arrested tuberculosis contracted while in service. S 702, introduced by Senator Kilgore, West Virginia, provides for the mobilization of the scientific and technical resources of the nation, establishing an Office of Scientific and Technical Mobilization. As used in the bill the term "scientific and technical personnel" means all persons, except physicians and dentists, who have completed any course of study in any college or university in any branch of science or its practical application or who have had not less than an aggregate of six months training or employment in any scientific or technical vocation. S 720, introduced by Senator Johnson, Colorado, and H R 1857, introduced by Representative Sparkman, Alabama, provide that during the present war and six months thereafter there shall be included in the Medical Departments of the Army and Navy such licensed female physicians and surgeons as the Secretary of War and the Secretary of the Navy may consider necessary. Those appointed will be commissioned, the bills propose, in the Army of the United States or the Naval Reserve and will receive the same pay and allowances and be entitled to the same rights, privileges and benefits as members of the Officers' Reserve Corps of the Army and the Naval Reserve of the Navy with the same grade and length of service. Female physicians and surgeons so appointed may be assigned only to duty in hospitals or other stations where female nurses are employed. H J Res 53, introduced by Representative Burdick, North Dakota, proposes that a major joint committee of the Senate and House be set up to take over the whole problem of handling proposed social security legislation. H R 1796 introduced by Representative Cunningham Iowa provides that nominal income from personal services may be disregarded in computing payments to be made as old age assistance and aid to the blind under the Social Security Act. H R 1798, introduced by Representative Johnson Indiana, provides protection against total permanent disability for persons granted national service life insurance. H R 1811, introduced by Representative Maas, Minnesota, proposes an appropriation of \$2,000,000 to expand facilities for the hospitalization of depen-

dents of personnel of the Navy and Marine Corps. The hospitalization of dependents of naval personnel at any naval hospital, the bill provides, will be on a per diem basis and all sums received in payment of such hospital charges will be deposited to the credit of the appropriation or fund for the maintenance and operation of naval hospitals. H R 1825, introduced, by request, by Representative Lesinski, Michigan, provides that all monetary benefits granted to veterans of World War I, and to their widows and dependents, be extended to the veterans of the present war, their widows and dependents. H R 1829, introduced, by request, by Representative Lesinski, Michigan, provides that the Administrator of Veterans' Affairs, within the limits of Veterans' Administration facilities, will be authorized to furnish necessary dental care and treatment to veterans of the present war who are not dishonorably discharged and who are not entitled to similar benefits under any law or veterans' regulation at the present time.

STATE MEDICAL LEGISLATION

Arizona

Bills Introduced—H 115 proposes the creation of a board of examiners for manual therapy, defined as a system of treatment wherein the muscles, joints, ligaments or tissues of the human body are moved or exercised by forces applied by the manipulator, assisted or supplemented by voluntary movements, by suggestion and advice, or by such mechanical, thermal, or electrical devices as may be required to facilitate normal movement or function of the joints ligaments and tissues of the person manipulated. H 146 proposes to require every physician attending a pregnant woman to take a sample of her blood not less than ten days after the first visit and to submit such sample to an approved laboratory for a standard test for syphilis.

Arkansas

Bills Introduced—H 194 proposes to make it unlawful for any one to use dynamite, nitroglycerin or other form of explosive within 2 miles of any private or public hospital. H 271 proposes to require every person applying for a marriage license to present a certificate signed by a qualified physician licensed to practice medicine and surgery certifying that the applicant is not infected with syphilis in a communicable stage.

California

Bills Introduced—A 1553 proposes to require all food handlers and domestic servants to obtain a certificate from a licensed physician and surgeon showing freedom from communicable diseases and to renew such certificate every three months. A 1608, to amend the revenue code proposes to exempt from the sales tax the sale of medicines, tonics and preparations sold as dietary supplements or adjuncts. A 1659 to amend the business and professions code, proposes to require vendors of prophylactics to renew their licenses annually. A 1729, to amend the penal code, proposes to require any person accused of intoxication or a crime involving intoxication to be examined by a licensed physician immediately on his being arrested, the duty of the physician being to determine whether or not the accused was in fact intoxicated. A 1782 proposes the enactment of a new uniform vital statistics act. A 1830, to amend the prenatal examination law, proposes to authorize chiropractors to obtain the required blood specimen. A 1831, to amend the labor code, proposes to authorize injured employees to receive the services of a chiropractor at the expense of the employer. A 1832 to amend the business and professions code, proposes to authorize schools teaching any of the healing arts to establish graduate courses of study in homeopathy, herbology, vitamin therapy, proprietary medicine

and drugs, minor surgery, materia medica, physical therapy, anesthesiology, obstetrics and certain other subjects. Graduates would be granted a degree of "physician" and would be entitled to practice the subjects taught in the graduate courses. A 1833, to amend the business and professions code, proposes to authorize any accredited school of medicine, surgery, osteopathy, chiropractic and any hospital to establish courses of training in nursing, the graduates of such courses to be known as graduate war nurses. A 1841, to amend the premarital examination law, proposes to authorize chiropractors to make the required certificate of exemption from venereal disease.

Georgia

Bills Introduced—H 135 proposes to require each person applying for a marriage license to furnish a certificate signed by a qualified physician licensed to practice medicine and surgery in any state or United States territory certifying that the applicant is not infected with syphilis in a communicable stage. H 136 proposes to require all licensed physicians attending a pregnant woman to take a sample of blood within thirty days of the first examination and to submit such sample to an approved laboratory for a serologic test for syphilis.

Idaho

Bills Enacted—H 24 has become chapter 26 of the Laws of 1943. This law requires every licensed physician attending a pregnant woman to take a sample of her blood at the time of the first examination and to submit such sample to a laboratory for a standard serologic test for syphilis. H 43 has become chapter 42 of the Laws of 1943. It provides that each applicant for a marriage license must produce a certificate signed by a licensed physician certifying that the applicant has been thoroughly examined and is not infected with syphilis in a communicable stage. The physician making the examination may not charge more than \$2. H 111 has become chapter 52 of the Laws of 1943. It exempts from the payment of any professional license or renewal fee all persons now holding such a license who are serving in the armed forces of the United States during the term of their military service.

Indiana

Bills Introduced—H 73 proposes to authorize the suspension of a driver's license on conviction of operating an automobile while under the influence of intoxicating liquor or narcotic drugs. H 294 proposes to authorize the division of public assistance to establish and maintain clinics for the care and treatment of eyes, under the supervision of an ophthalmologist or eye specialist who shall be a doctor of medicine licensed to practice medicine in the state. H 462 proposes, in effect, that physicians' records shall be competent evidence in court if the custodian testifies to the identity and mode of preparation of the record and if the records were made in the regular course of business.

Iowa

Bills Introduced—S 68 to amend the divorce law, proposes to authorize the granting of a divorce when one of the parties to a marriage has been totally insane for a period of five years and there is no reasonable hope of recovery. S 219 proposes that when a person has been arrested for operating a motor vehicle while intoxicated a sample of such person's blood or urine may, with the consent of the person so charged be taken by a duly licensed physician and subjected to chemical analysis, the results of which analysis shall be receivable in evidence. The fact of refusal by a person to permit a sample of blood or urine to be taken will likewise be admissible in evidence.

Kansas

Bill Introduced—H 293 to amend the osteopathic practice act proposes to extend the scope of osteopathic practice so as to authorize licentiates to practice as physicians and surgeons of the osteopathic school of medicine which shall include the right to practice operative surgery with instruments, and obstetrics to prescribe and administer narcotics, analgesics, anodynes, anesthetics, antiseptics, antidotes, serums, vaccines and biologicals and to have the same rights as practitioners of other schools

of the healing art with respect to rendering services under the provisions of laws relating to health insurance, workmen's compensation, control of infectious diseases and care of the indigent.

Michigan

Bills Introduced—S 113, to amend the medical practice act, proposes to authorize the Michigan state board of registration in medicine to suspend in whole or in part the educational requirements prescribed by the act at any time during the state of war now existing between the United States and various other nations. H 166 proposes to authorize the boards of supervisors of certain counties throughout the state to provide group life, health and accident and/or hospitalization insurance for the employees of such counties.

Montana

Bills Introduced—S 73, to amend the chiropractic law, proposes to extend the scope of chiropractic practice to include physiotherapy, electrotherapy, hydrotherapy, proctology and minor surgery and to require chiropractors to be examined in such subjects. H 118, to amend the medical practice act, proposes, among other things, to authorize the board of medical examiners to prescribe and enforce reciprocity requirements current with changes in standards of the practice of medicine and surgery.

Bill Passed—S 97 passed the senate on February 11. It proposes to relieve physicians in the military service of the United States from paying annual license fees during the period of such service.

New York

Bill Introduced—S 528, to amend the public health law, proposes to require domestic servants to furnish a certificate from a duly licensed and registered physician certifying freedom from tuberculosis and from any venereal disease.

Ohio

Bills Introduced—H 54 proposes to exempt from the sales tax the sales of prescription medicines. H 78 to amend the medical practice act, proposes that administering to human ills through prayer or spiritual means alone in accordance with the tenets or creed of any religious denomination for a fee or compensation shall not be regarded as practicing medicine. H 112, to amend the osteopathic law, proposes the creation of a state osteopathic examining board to take the place of the existing osteopathic examining committee. H 113, to amend the law relating to municipal hospitals, proposes that in the management and control of municipal hospitals there shall be no discrimination against any physician, or the patient of any physician, who holds a certificate to practice in Ohio, whether it is medicine or surgery, or osteopathy or chiropractic. H 167, to amend the premarital examination law, proposes that when one of the applicants is in the military service of the United States his physical certificate may be signed by a commissioned medical officer of the military service.

Oklahoma

Bills Introduced—S 98 proposes to authorize a physician legally qualified to practice in the state of Oklahoma to perform a postmortem cesarean section when the physician has reason to believe that the child is viable in the mother. In the performance of such operation, the physician shall not be liable either civilly or criminally even though the operation is performed without the consent or even against the protest of those in whom the law has recognized a legal right of possession of the body of the deceased provided only that the operation is performed in good faith and with due skill and without unnecessary injury or mutilation. H 37 proposes to authorize the state and local health officers to examine arrested persons to determine whether or not they are infected with a venereal disease and if found infected, to quarantine such persons for the purpose of treatment.

Pennsylvania

Bills Introduced—H 236 proposes that for the duration of the war a minimum of nine months rather than one year internship shall constitute the necessary legal training to qualify for admission to examination for a license to practice medicine.

and surgery in Pennsylvania H 235 proposes to authorize the state board of medical education and licensure to issue temporary certificates to physicians licensed in other states to authorize them to practice medicine and surgery in Pennsylvania for the duration of the present war and six months thereafter

South Carolina

Bill Enacted—H 33 has become Governor's Act No 11 of the Laws of 1943 This law eliminates from the medical practice act the requirement that no two of the required four full courses of lectures may be given in the same year The purpose of this law is to enable graduates of accelerated medical courses to obtain licensure in South Carolina

South Dakota

Bills Introduced—S 129, to amend the basic science act, proposes to exempt from the provisions of the act any person acting as an assistant or under the supervision and direction of a person holding a basic science certificate S 186 proposes an appropriation for the purchase and installation of hydrotherapy equipment in the state hospital for the insane H 206 proposes to authorize the sterilization of inmates of the state hospital on recommendation of the superintendent when it is shown that the inmate suffers from certain mental diseases, perversion or diseases of a syphilitic nature and that the person is capable of procreation Provision is also made for the voluntary sterilization of any inmate H 207 proposes to authorize the granting of the writ of habeas corpus to persons having a "psychopathic personality," defined as the existence of such conditions of emotional instability and impulsiveness of behavior and lack of customary standards of good judgment, or failure to appreciate the consequences of his acts or a combination of any such conditions, as to render such person irresponsible for his conduct with respect to sexual matters or in respect to matters relating to acts and conduct of a criminal nature and thereby dangerous to other persons

Tennessee

Bill Introduced—H 198 proposes to provide for the sterilization of inmates of certain state institutions when it has been determined that procreation by such inmate is inadvisable The determination must be unanimously made by a physician, a psychologist, a sociologist and an officer of the institution in which the inmate is confined

Bills Enacted—S 77 has become chapter 44 of Public Acts of 1943 It provides that all persons employed as food handlers must procure a health certificate, including a Wassermann test, signed by a physician licensed to practice in the state of Tennessee, which certificate must be renewed annually S 160 has become chapter 73 of Public Acts of 1943 It provides that every physician who makes a diagnosis of or treats or prescribes for a case of venereal disease, including syphilis, gonorrhea and chancroid, shall report such case immediately to the full time municipal health officer S 300 has become chapter 26, Public Acts of 1943 It authorizes the coroner, when requested so to do by the district attorney, to summon a physician or surgeon to examine a person or to perform an autopsy thereon and to give his professional opinion as to the cause of death The fee of such physician shall be limited to \$25 H 76 has become chapter 92 of the Public Acts of 1943 It provides for the creation of a board of examiners in the basic sciences of anatomy, physiology, chemistry, bacteriology and pathology Exempted from the operation of the act would be osteopaths, chiropractors, if they do not possess, prescribe or administer drugs, as well as dentists, naturopaths, nurses, midwives, optometrists, chiropodists, barbers, cosmeticians, or Christian scientists practicing within the limits of their respective callings

Washington

Bills Introduced—S 167, to amend the basic science act, proposes that the existing examining committee be dissolved and that a new committee be created to be composed of one member from each school of practice licensed in the state of Washington Under the existing law the members of the examining committee are chosen from the faculty of the University of Washington and Washington State College H 238 proposes to exempt chiropractors from the basic science law

West Virginia

Bill Introduced—H 230 proposes, among other things, to require every physician who examines or treats a person having syphilis, gonorrhea or chancroid to instruct such person in measures for preventing the spread of the disease and to inform such person of the necessity of taking treatment until cured If the person fails to report for treatment, the physician must make a report of such fact to the local health officer

WOMAN'S AUXILIARY

Florida

The Woman's Auxiliary to the Duval County Medical Society voted a contribution to the WPA Nursery, on recommendation of the philanthropic chairman, Mrs John H Mitchell Plans were made for a supper to be given for service men at the WJAX recreation center Officers of the auxiliary are Mrs J W Hayes president, Mrs E W Veal vice president, Mrs L M Wachtel secretary and Mrs G H Ira treasurer

Georgia

The Woman's Auxiliary to the Fifth District Medical Society held its semiannual meeting at the Academy of Medicine on West Peachtree Street in Atlanta Mrs J Harry Rogers, manager, presided Mrs J Lon King of Macon, president of the Woman's Auxiliary to the Medical Association of Georgia, was the honor guest of the evening A program was presented by the medical staff of the Lawson General Hospital

Indiana

The Allen County medical auxiliary had Dr L Potter Harshman as its speaker at the Lutheran Hospital His subject was "Psychiatry in the Present Crisis" Mrs Elmer C Singer presented recent legislation

Since January the Woman's Auxiliary to the Orange County Medical Society has had five meetings, supper meetings at the homes of members, at which problems concerning the county

medical society were discussed at the table Members have done more than their share of the war program activities One of its members taught a Home Nursing class The main project for the year was the promotion of a wider circulation of "Hygeia" A survey of all doctors' and dentists' offices, schools, libraries and beauty parlors was made Fifteen subscriptions were obtained

Minnesota

The Hennepin County auxiliary has two new projects under way One is the Red Cross dressing group, which, although organized last year, did not function until this year owing to lack of supplies Mrs J P Hiebert is chairman with Mrs J M Hall co-chairman The second activity is the staffing of a War Saving Stamp booth in the Medical Arts lobby with Mrs Hugh Tunstead in charge Both projects are carried on with the cooperation of the dental auxiliary

Utah

In December a luncheon was held at the home of Mrs Silas S Smith, president of the auxiliary to the Utah State Medical Association, for officers of the state organization The guest was Mrs Frank N Haggard of San Antonio, Texas, President of the Woman's Auxiliary to the American Medical Association Her message was for the members to give their time and effort in self education to help in the war effort Fifty members were present

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Dr King Observes Ninetieth Birthday—Dr. John C. King, Pasadena, formerly president of the California Medical Association, observed his ninetieth birthday, February 9. Dr. King, who has been in retirement since 1923, graduated at the University of Nashville Medical Department, Nashville, Tenn., in 1874. He had been president of the high school board in Banning for twenty years and was one of the founders of the San Bernardino County Medical Society, serving as its president and earlier of the Riverside County Medical Society and the state board of medical examiners.

New Virus Diagnostic Unit—The division of laboratories of the state department of public health recently established a virus diagnostic unit to render assistance to physicians of the state in the diagnosis of certain neurotropic virus diseases, including at present western equine encephalitis and St. Louis encephalitis and probably later lymphocytic choriomeningitis. All health officers, physicians and hospitals wishing assistance or confirmation in the diagnosis of these diseases may send specimens to and obtain containers from the State Department of Public Health, Division of Laboratories, Virus Unit, 1390 University Avenue, Berkeley. A supply of containers will be available at city health departments soon.

Assistant Medical Director and Superintendent Needed—The California State Personnel Board on February 9 announced examinations to be held soon for the positions of assistant medical director and superintendent at a mental hospital. The position of assistant medical director has a salary range from \$260 to \$340 a month plus maintenance for self and family. Entrance requirements include possession of a license to practice as a physician and surgeon, graduation from a medical school and three years of medical practice, two years of which shall have been in a mental hospital. The position of superintendent of the mental hospital has a salary range of \$360 to \$440 plus complete maintenance for self and family. Qualifications must include possession of a license to practice as a physician and surgeon, graduation from medical school and five years of medical experience in a mental hospital. Candidates who are successful in the examination must secure a license to practice as a physician and surgeon in California before they can be considered eligible for appointment except that any such candidate who has applied for a California license may be appointed for a period of not more than one year. Official application forms may be obtained from the offices of the state personnel board, 1015 L Street, Sacramento. The final date for filing applications is March 10.

Langley Porter Clinic Dedicated—The Langley Porter Clinic at the University of California Medical School, San Francisco, was opened with appropriate ceremonies on February 13. The outpatient department was named in honor of the late Dr. Aaron J. Rosanoff, who at the time of his recent death was director of the state department of institutions and was to a large measure responsible for the building of the Langley Porter Clinic. Mrs. Dora Shaw Heffner, Los Angeles, director of the state department of institutions, presided at the morning session. Among the speakers were:

Dr. Walter L. Treadway, Los Angeles Memorial to Dr. Aaron J. Rosanoff.

Dr. Glenn E. Myers, Los Angeles. Dr. Aaron J. Rosanoff.

Dr. Fred O. Butler, Eldridge. The Langley Porter Clinic and Its Relationship to the State Department of Institutions.

Dr. Thomas W. Hagerty, Camarillo. The Work of the California State Hospitals in the Prevention and Treatment of Mental Disorders.

Dr. Langley Porter, San Francisco. Potential Contributions of a Psychiatric Hospital in a Total University Setting.

Harry M. Casady, Berkeley. Psychiatry and Social Work.

Mrs. Jean W. MacFarlane, Berkeley. Psychiatry and Clinic Psychology.

Miss Margaret A. Tracy, Berkeley. Psychiatry and Nursing.

Robert G. Sproul, LL.D., president of the University of California, Berkeley, presided at the evening session in Toland Hall at the University of California Hospital, at which speakers all of San Francisco were:

Dr. Francis S. Smyth, Psychiatry and Pediatrics.

Dr. William J. Kerr, Psychiatry and General Medicine.

Dr. Howard C. Naffziger, Neurological Surgery and Its Relations.

Dr. Karl M. Bowman, Psychiatry and the Langley Porter Clinic.

The new clinic is a neuropsychiatric unit of the state department of institutions, named in honor of Dr. Langley Porter, dean emeritus and professor of medicine and lecturer in medical history and bibliography emeritus of the medical school.

DELAWARE

Society News—Dr. Harry C. Bacon, Philadelphia, discussed the diagnosis and treatment of common rectal diseases before the Newcastle County Medical Society in Wilmington, January 19. Dr. Edgar R. Miller, Wilmington, addressed the society recently on "The Uses and Limitations of the Electrocardiogram." Dr. John T. Hynes, Wilmington, discussed "Carcinoma of the Cervix" before the society on February 16.

Deputy State Health Officer Needed—The Merit System for Personnel Administration in Delaware is accepting applications for the position of deputy state health officer in the state board of health. The salary range for the position is \$3,600 to \$4,200 and applications will be accepted until further notice. The applicant must show graduation from an approved medical school, internship of one year in a hospital approved for internship by the American Medical Association, license to practice medicine and be qualified for licensure in Delaware. The applicant must have had one year in a school of public health of recognized standing prior to or within a period of three years from the date of employment, and at least two years full time paid professional experience in the field of public health. Preference will be given to persons having a degree in public health. The applicant must be not more than 35 years of age when beginning public health work. Additional information may be obtained from Merit System of Personnel Administration, 512 Continental American Life Building, Wilmington.

ILLINOIS

Social Hygiene Day—On February 3 the state department of health and the state department of public welfare jointly sponsored a statewide observance of social hygiene day. This is the first year the welfare department took part in this observance. On February 3 the first of six regional conferences on venereal disease control for public health nurses was held at Joliet. Others were planned for Dixon, Springfield, Champaign, Herrin and Centralia.

Test Case Ruling Affects Alien Applicants for Examination in Medicine—In a test case, January 22, Judge John Prystalski in circuit court, upheld the right of the state department of registration and education to forbid the taking of examinations by persons from European schools newspapers reported. The decision in effect barred more than 150 graduates of European medical schools from practicing medicine who had applied for permission to take the state examinations in April. The test case covered the ruling of the state board of examination adopted June 2, 1942, which prohibited graduates of medical colleges in continental Europe and graduates of the extramural colleges of Scotland and Ireland who finished after July 1, 1936. Switzerland graduates were excepted. This rule is to be in force until a true evaluation of the colleges referred to may be obtained, at which time such nonaccredited foreign colleges will be required to prove to the department that their courses and equipment are in every way equal to American medical colleges accredited by the department of registration and education. In dismissing the suit Judge Prystalski is reported to have said that he had no authority to interfere with administrative regulations of the department.

Chicago

Ludvig Hektoen Lecture—Dr. Lloyd F. Craver, New York, will deliver the nineteenth Ludvig Hektoen Lecture of the Frank Billings Foundation on March 26 at the Palmer House under the auspices of the Institute of Medicine of Chicago. Dr. Craver will discuss "The Diagnostic Problems of Early Cancer."

The Capps Prize—The Institute of Medicine of Chicago announces that the Joseph A. Capps Prize for Medical Research for 1942 has been awarded to Dr. Mary E. Martin who graduated at Northwestern University Medical School in 1941 for her investigation on "Distribution of Nerves in the Adult Human Myometrium." The prize is awarded annually to a young graduate of a Chicago medical school for the most meritorious investigation in medicine or in the specialties of medicine.

Course in Ear, Nose and Throat—A refresher course in laryngology, rhinology and otology will be held at the University of Illinois College of Medicine, March 22-27. To meet the needs of ear, nose and throat specialists who, under existing conditions are able to devote only a brief period to postgraduate review study, this didactic and clinical course has been arranged. Registration is limited. The fee for the complete course is \$50. Letters requesting application for registration should include school and year of graduation also details concerning specialty training and experience. Address: Department of Oto-Laryngology, University of Illinois College of Medicine, 1853 West Polk Street.

INDIANA

Society Arranges Night Service for Public—On January 10 a plan of answering emergency night calls was begun by the Indianapolis Medical Society, according to the bulletin of the society. The medical society has an unlisted telephone number (Rt. 4796) which is answered by a member of the society who has volunteered for this service. The members of the society may refer calls to this number when they do not wish to make them. This service is in operation from 8 p. m. until 7 a. m. daily. The calls are made by house officers of the Indianapolis City Hospital. The fee is \$5 for calls inside the city and 25 cents a mile additional charge for calls outside the city. The doctor who answers the telephone asks the person calling who referred them to this number. If the call is received before 11 p. m. the referring doctor is called to verify the fact that he does not wish to make this call. If the call is received after 11 o'clock the doctor is not called until the next morning. If the person calling is unable to pay, he is referred to the Indianapolis City Hospital. Obstetric calls are handled by the Outdoor Obstetrical Service of the city hospital. If in the opinion of the visiting physician the patient needs immediate hospitalization, the patient is sent to a private hospital and it is then the duty of the hospital to call the proper physician from its staff. Patients are always told that this is an emergency service and that no return calls will be made. They are referred to their family doctor or, if they do not have a family doctor, they are given a list of the members of the society who are practicing in their vicinity.

LOUISIANA

Changes in Health Officers—Dr. Abraham Oppenheim Arcadia, director of the Bienville Parish Health Unit, has been appointed in charge of the units in Vernouilion and New Iberia parishes.—Dr. Roy A. Kelly, New Roads director of the St. Charles Parish Health Unit, was recently assigned in charge of the Jefferson Davis Health Unit.

Graduate Medical Assembly—The seventh annual New Orleans Graduate Medical Assembly will be held at the Roosevelt Hotel, New Orleans, March 15-18. The program will include lectures, clinics, symposiums, clinicopathologic conferences, scientific and technical exhibits, medical motion pictures and round table luncheons. Among the speakers who will discuss one or more papers will be:

Dr. Tinsley R. Harrison Winston Salem N. C.
Dr. Robert J. Crossen St. Louis
Dr. James G. Townsend Bethesda Md.
Sister Elizabeth Kenny Minneapolis
Lieut. Col. Edgar V. Allen M. C. Army of the United States
Dr. Louis Hamman Baltimore
Lieut. Col. Roy Glenwood Spurling M. C. Army of the United States
Dr. Ralph I. Lloyd Brooklyn
Dr. Nicholson J. Eastman Baltimore
Dr. Edwin W. Ryerson Chicago
Dr. John J. Shea Memphis
Dr. Howard T. Karsner Cleveland
Dr. Erling S. Platow Minneapolis
Dr. Fred J. Hodges Ann Arbor Mich.
Dr. Warren H. Cole Chicago
Major Rettig Arnold Griswold M. C. Army of the United States
Dr. Charles B. Huggins Chicago

MASSACHUSETTS

State Meeting to Be in Boston Instead of Springfield—The Massachusetts Medical Society will hold its annual session at the Hotel Statler Boston May 25-26, instead of at the Hotel Kimball, Springfield, May 18-19.

Dr. Symonds to Give the Dunham Lectures—Dr. Charles Putnam Symonds, Air Commodore in the Royal Air Force and consultant in neurology, will deliver three lectures at Harvard Medical School Boston, under the Edward K. Dunham Lectureship for the Promotion of the Medical Sciences, on "The Human Response to Flying Stress." The separate lectures will be March 10, "The Two Sides of the Problem," March 11, "The Foundation of Confidence," and March 12, "Air Crew Selection and Maintenance."

Dr. Landis Named as Professor of Physiology at Harvard—Dr. Eugene Markley Landis, professor of internal medicine at the University of Virginia Department of Medicine, Charlottesville has been appointed George Higginson professor of physiology at Harvard Medical School, Boston, filling the vacancy that occurred on the retirement of Dr. Walter B. Cannon, Cambridge. The appointment will be effective July 1. According to the *Harvard Medical Alumni Bulletin*, although Dr. Landis is an internist most of his researches have been essentially physiologic in nature or have concerned basic physiologic principles in medical conditions. In 1926 Dr. Landis graduated at the University of Pennsylvania School of Medicine Philadelphia where he was in 1931

associate in medicine and in 1934 assistant professor. He has been professor of medicine at the University of Virginia since 1939. In 1936 he received the John Phillips Memorial Medal of the American College of Physicians.

MICHIGAN

New District Health Unit—Leelanau County has joined with the Grand Traverse county department of health to form a new district organization. Dr. Buell H. Van Leuven, Traverse City, will be in charge. The Grand Traverse unit has functioned since April 1939.

Koch Trial Opened—The federal government's trial against Dr. William F. Koch and his brother Louis on charges of violating the Federal Food Drug and Cosmetic Act opened in Detroit January 12. Dr. Koch has long been identified with an alleged cancer cure. The two Kochs are respectively, president and secretary of the Koch Laboratories, Inc., Detroit, promoters of various products including treatments sold for cancer and other conditions. The federal charge is that three preparations of the Koch Laboratories have been shipped from Detroit to other states with false and misleading labels which made representations that could not be justified by facts. The *Detroit Sunday Times*, January 10, reported that a federal trade commission action against the brothers is pending awaiting the outcome of the Food Drug and Cosmetic Act case. Dr. Koch first announced his so-called cancer cure in 1919 the year following his graduation at the Detroit College of Medicine. Later his claims extended to "cures" for allergies and infections. In 1933 he moved to Delray Beach, Fla., and operated a clinic there, while his brother Louis managed the laboratories in Detroit.

Annual Lecture Marks Dedication of Beaumont Room—Col. Edgar Erskine Hume, M. C., U. S. Army, Washington D. C., delivered the twenty-second annual Beaumont Lecture before the Wayne County Medical Society, Detroit February 15, on "Contributions of U. S. Army Medical Officers to Science." The occasion marked the dedication of the Beaumont Room in the David Whitney House, the headquarters of the county medical society, the official ceremonies preceding the lecture which was delivered at the Art Institute. A portrait of William Beaumont by Deane Keller of the Yale School of Fine Arts, New Haven, Conn. was unveiled at the Art Institute and subsequently placed in the Beaumont Room at the society headquarters. "Beaumont and St. Martin" one of the series of paintings executed by Dean Cornwell, New York was displayed for the occasion. The Beaumont Room was set aside last year for memorabilia (*THE JOURNAL*, July 25, 1942 p. 1033). The present collection includes contemporary miniatures of Dr. and Mrs. Beaumont made available by Mrs. May Beaumont Brotherton of Green Bay, Wis. and her sister, Mrs. Ruth B. Brown of Iron River and a number of rare medical books including a first edition of "Experiments and Observations on the Gastric Juice and the Physiology of Digestion."

NEW JERSEY

Honorary Degrees Conferred—The New Jersey College of Pharmacy at Rutgers University awarded honorary degrees to the following at graduation exercises in the auditorium of the Mutual Benefit Life Insurance Company on January 6: Dr. Morris Fishbein, Chicago, Editor of *THE JOURNAL*; Dr. Thomas M. Pascall, Newark, chief surgeon of Public Service Corporation and medical consultant of Fidelity Union Trust Company, and Adolph F. Marquer, Newark, pharmacist. George D. Beal, Ph.D., Pittsburgh, recipient of the Remington Medal in 1941 for the greatest contribution to pharmacy during the year, received the honorary degree of doctor of science.

Dr. Bingham Receives Award—Dr. Arthur W. Bingham, East Orange chairman of the committee on maternal welfare of the Medical Society of New Jersey for twelve years, was presented with the fourth Dr. Edward J. III Award by the Academy of Medicine of Northern New Jersey. The award is a bronze plaque given to a physician by the academy at such time as it deems it wise who merits it for extraordinary service as a physician and a citizen. It was established by the academy to honor its first president Dr. Edward J. III who died last year. Dr. Bingham graduated at Columbia University College of Physicians and Surgeons New York in 1896.

"Sanitation Wardens" Organized—A new volunteer civilian corps to be known as "Sanitation Wardens" was organized at a meeting of the health committee of the community war services division in Plainfield recently. Sanitation wardens according to the sponsor of the plan, Mr. Andrew J. Krog, health officer of Plainfield will be allocated to city districts according to the number of eating and drinking estab-

inments within the confines of a district. They will be deputized to make inspections of establishments where food and drink are sold on the premises for consumption and possibly later for the investigation of sanitation nuisances generally. The wardens will not have the power to take official action but will report back to the health department from whose office they will operate, they will in effect be junior assistants to paid health inspectors. A regular training course has been devised to include a series of lectures, demonstrations and movies and, as part of the training, volunteers will accompany regular health inspectors during their daily check-ups.

NEW YORK

Anatomist Dies—Charles Howell Ward, Rochester founder of the Charles H. Ward Anatomical Laboratory and pioneer commercial anatomist, died January 18, aged 80. Mr. Ward was a member of the Rochester Dental Society and of the Seventh District group of the New York Dental Society.

Graduate Lecture—Dr. Foster Kennedy, New York, will discuss 'Nervous Conditions Associated with Warfare' in Ithaca before the Tompkins County Medical Society on March 16. The lecture is part of a postgraduate program sponsored by the state medical society and the state department of health.

Survey of Child Care Need—Authorization has been given to one hundred and eight local war councils in the state to make an immediate canvass in their territories to find out the number of mothers having children under 16 who are engaged in work in war plants and the number of children affected. The work is being carried out at the request of Governor Thomas E. Dewey to lay the ground work for his plan to establish child care centers wherever necessary.

New York City

Dr. Hirsh Honored—On January 28 a dinner was held at the Hotel Savoy-Plaza to honor Dr. A. Bern Hirsh on his retirement as managing editor of the *Journal of the Medical Society of the County of New York*. Dr. Charles Gordon Heyd was toastmaster. Other speakers included Dr. Edward C. Titus and Col. Samuel J. Kopetzky, M. C., U. S. Army, who paid tribute to Dr. Hirsh for establishing the *New York Medical Week* and his service to its successor the *Journal of the Medical Society of the County of New York*. In 1905 Dr. Hirsh founded the *Weekly Roster and Medical Digest* now known as *Philadelphia Medicine* and served as its editor until 1917.

Health Codes for Day Nurseries—The city board of health has adopted a new health code for day nurseries which are caring for an increasing number of children as mothers enter industry. The new regulations include an annual physical examination for each staff member, examination of each child when admitted and every six months thereafter and provision for feeding the children every four hours according to a diet prepared by the health department. The food, milk and kitchen equipment of the nurseries will be strictly inspected. Minimum play, rest and sanitary space, depending on the registration, are prescribed. Each agency also must prove its financial competence to comply with the standards.

"Arts in Therapy"—The Museum of Modern Art opened an exhibition to the public on "The Arts in Therapy," February 3. The exhibition will later circulate through the country. Last fall the museum, in cooperation with Artists for Victory, held a competition in which artists and craftsmen all over the nation were asked to submit new designs and objects that might be utilized in art therapy. The twenty-three entries which received prizes of \$500 are included in the display. James Thrall Soby, director of the museum's armed services program, said the "exhibition has been designed to encourage and broaden the use of the various arts and crafts in therapeutic work among disabled and convalescent members of the armed forces." The exhibition has been divided into two sections. The first section comprises objects and projects related to those crafts which have been found of therapeutic and recreational value to patients. In the second section is illustrated the use of drawing, painting and sculpture in therapy conducted from the psychiatric point of view as a means both of diagnosis and of cure. The first or occupational therapy section of the exhibition includes more than a hundred items in the various crafts, such as weaving, woodworking, paper construction, metal work, pottery, toys and similar objects that might be made by physically handicapped men.

Centennial of Holmes's Paper on Puerperal Fever—The one hundredth anniversary of the publication by Oliver Wendell Holmes of his paper on "The Contagiousness of Puerperal Fever" was observed at the New York Academy of Medicine February 19. 'The Family Faces the Future' was the theme of the morning program with the following speakers: Mr. Lawrence K. Frank, chairman of science, National Resources

Planning Board, Dr. Abraham A. Brill, Stanley P. Davies, Ph.D., executive director, Community Service Society of New York, and Dr. Frank Fremont-Smith. The theme of the luncheon conference was "Maternity and the Changing Family Scene" with Louis I. Dublin, Ph.D., chief statistician and third vice president of the Metropolitan Life Insurance Company, Dr. Alan F. Guttmacher, Baltimore, and Miss Hazel Corbin, general director, Maternity Center Association, Inc. There was an afternoon symposium on "Meeting the Problems of Maternity Welfare and Child Health Along Many Fronts" by the following speakers:

Miss Alta E. Dines, Community Service Society of New York; Miss Frances Taussig, Federation for the Support of Jewish Philanthropic Societies of New York City; Mrs. Sidonie M. Gruenberg, Child Study Association of America, Inc.; Mr. D. Kenneth Rose, Planned Parenthood Federation of America, Inc.; Dr. Thomas W. Patrick Jr., New York Urban League, Inc.; Dr. Leon Baumgartner, New York City Department of Health; Dr. Elizabeth M. Gardiner, Albany, New York State Department of Health; Mrs. Shepard Kreeh, Maternity Center Association, Inc.; Dr. Herbert B. Wilcox, New York Academy of Medicine.

At the evening meeting Dr. Arthur Z. Chace, president of the academy, gave the address of welcome and Dr. Richard N. Pierson, chairman of the Holmes Centenary Committee, presided. Dr. Reginald Fitz, Boston, spoke on "My Doctor Holmes" and Dr. Benjamin P. Watson, director of the Sloane Hospital for Women, discussed "Oliver Wendell Holmes—A Century's Vindication of His Work on Puerperal Fever."

OHIO

New Heart Station—The Max Stern Heart Station has been established in Cincinnati through a gift of Mrs. Martha S. Stern in memory of her husband. Approved by the Cincinnati Board of Health, the new station will be conducted under the supervision of a committee appointed by the Heart Council. Dr. Bernice L. G. Wedum, Cincinnati, on the staff of Children's Hospital, has been appointed clinician of the heart station.

Outbreak of Smallpox—Six additional cases of smallpox reported to the Ohio State Department of Health for the week ended January 17 brought the total to 27 since the outbreak in December according to the *Columbus Citizen*, January 17. Three of the new cases were reported from Holmes County, where an outbreak occurred in the Amish settlement. The outbreak in Ohio and the one in Pennsylvania (THE JOURNAL, January 2, page 61) were related when it was found that the wife of an Amish minister became ill with the disease following their return from a trip into Pennsylvania, Maryland and Delaware.

Personal—Dr. Richard T. Morgan has been appointed coroner of Marion County to succeed his son Dr. Richard L. Morgan, who has entered military service—Lieut. Comdr. William McKinley Johnston, M. C., on leave from the U. S. Naval Reserve after serving at Guadalcanal, was guest of honor at a dinner in the Akron City Club, January 6—Dr. Alexander S. McCormick, Akron, who recently retired as secretary of the Summit County Medical Society after serving the society in various capacities for twenty-eight years (THE JOURNAL, January 23), was presented with a wrist watch at the January meeting by Dr. James G. Kramer, Akron, the outgoing president—Dr. Hugh J. Means, Columbus, has been promoted to professor of roentgenology in the department of surgery and full time director of the x-ray laboratory in the Stirling-Loring University Hospital.

OKLAHOMA

Institutes in Wartime Industrial Health—The Oklahoma State Medical Association and the state department of public health are cooperating in two institutes on wartime industrial health, one to be held in Tulsa at the Mayo Hotel, March 18, and one in Oklahoma City at the Biltmore Hotel, March 19. Dr. Henry C. Weber, Bartlesville, will open the program with a discussion on the "Purposes and Objectives of the Program on Industrial Health of the Oklahoma State Medical Association." Members of the state department of public health will discuss "Technical Assistance of the State Health Department Available to Industry." Among other speakers on the program will be:

J. J. Bloomfield, Bethesda, Md., Industrial Hygiene in War Production; Dr. Carl M. Peterson, Chicago, Secretary, Council on Industrial Health; American Medical Association; General Relation of Medicine to Industry; Dr. Clarence D. Selby, Detroit, Preemployment Examination and Placement; Dr. William A. Sawyer, Rochester, N. Y., Conservation of Industry's Manpower; Dr. John Albert Key, St. Louis, Medical Legal Phase and Evaluation of Disability; A. G. Hewitt, Chicago, Management Looks at Industrial Health; Dr. Louis Schwartz, Bethesda, Md., Occupational Diseases and Their Control.

PENNSYLVANIA

Society News—Dr Abraham H Aaron, Buffalo, discussed "Use of Drugs by the General Practitioner" before the Northampton County Medical Society recently—A symposium on the eruptive fevers was conducted before the Westmoreland County Medical Society, March 2, in Greensburg

Philadelphia

A Million Persons Vaccinated—On January 25 the Philadelphia *Enquirer* reported that the total vaccinations in the city's drive to prevent the spread of smallpox had reached more than 1,000,000. A reported total of 102,393 persons had been vaccinated in health centers, emergency stations and schools under the supervision of the city department of health since the program was inaugurated January 2. In addition, private physicians inoculated thousands more in their offices, in industrial plants, in hospitals and among the membership of various organizations. The drive against smallpox started following the outbreak in an Amish settlement in the Kishacoquillas Valley (THE JOURNAL, January 2, p 61)

VIRGINIA

Awards for Research in State Hospitals—To stimulate interest in professional work among the physicians on the staffs of the state hospitals, exclusive of the superintendents, prizes will be given each year for original or meritorious papers, based preferably on observations of patients under the physicians' care. The state hospital board, with the approval of the governor, has arranged to make available \$500 each year for these awards, \$250 for the first award, \$150 for the second, \$75 for the third, and \$25 for an honorarium to some out of state authority who would pass on the relative merit of the papers. The papers may concern either one unusual case or a group of cases. The diseases discussed may be common or ordinary diseases in which careful study of the cases will bring out some new points. The papers need not necessarily deal entirely with the clinical or laboratory features but may cover reclassifications and deductions that have not heretofore been made. The papers should be handed to Dr Hugh C Henry, Richmond, state commissioner of mental hygiene and hospitals, by the first of June of each year and the awards made by the first of October.

GENERAL

National Negro Health Week—National Negro Health Week will be observed throughout the country April 4-11. This year the theme will be "Health on the Home Front—Victory on the War Front."

Examinations in Ophthalmology—The American Board of Ophthalmology announces that 1943 examinations will be held in New York, June 4-5, and Chicago, October 8-9. Application blanks may be obtained from the secretary of the board, Dr John Green, 6830 Waterman Avenue, St. Louis.

Examination of Medical Technologists—The Registry of Medical Technologists of the American Society of Clinical Pathologists announces that its spring examination will be held April 30, the closing date for the acceptance of applications to be March 10. Additional information may be obtained from Dr Lall G Montgomery, chairman of the board of registry, 2400 University Avenue, Muncie, Ind.

Officers of Federation of State Boards—Dr John F Hassig, Kansas City, Kan., secretary of the Kansas Board of Medical Registration and Examination was chosen president-elect of the Federation of State Medical Boards during its annual meeting in Chicago, February 16 and Dr Frank M Fuller, Keokuk, Iowa, chairman of the Iowa Board of Medical Examiners, was inducted into the presidency. Dr Adam P Leighton, Portland, Maine, secretary of the Maine Board of Registration of Medicine, was named vice president and Dr Walter L Biering, Des Moines, state health commissioner of Iowa, was reelected secretary-treasurer.

Obstetric Examination in Pittsburgh—The general oral and pathologic examinations (part II) for all candidates will be conducted in Pittsburgh by the entire American Board of Obstetrics and Gynecology from Wednesday, May 19, through Tuesday, May 25. Headquarters will be at the Hotel Schenley for the board and formal notice of the exact time of each candidate's examination will be sent him several weeks in advance of the examination dates. Hotel reservations may be made by writing directly to the hotel. Candidates for reexamination in part II must make written application to the secretary's office not later than April 15. The Office of the Surgeon General of the U S Army has issued instructions

that men in service eligible for board examinations be encouraged to apply and that they may request orders to detached duty for the purpose of taking these examinations whenever possible. Candidates in military or naval service are requested to keep the secretary's office informed of any change in address. Deferment without time penalty under a waiver of the published regulations applying to civilian candidates will be granted if a candidate in service finds it impossible to proceed with the examinations of the board. Applications are now being received for the 1944 examinations. For further information and application blanks address Dr Paul Titus, secretary, 1015 Highland Building, Pittsburgh.

Americans Do Not Eat Wisely, Says Gallup Poll—A nationwide survey conducted by the American Institute of Public Opinion to determine how much the average American adult knows about simple nutrition rules revealed that the average American has much to learn about what to eat. The New York *Times* reported on February 8. A record of the principal foods eaten by representative adults in all states was compared with a list of essential health foods recommended by the Bureau of Home Economics of the Department of Agriculture and other nutrition experts. The following figures represent the number of persons who had none at all of the foods listed as necessary daily in each category.

Fruits and raw greens	tomatoes	citrus fruits or juices	raw cabbage
or salad green	45 per cent	had none	
Eggs	one a day	48 per cent	had none
Milk and cheese	34 per cent	had none	
Vegetables	leafy green or yellow	25 per cent	had none
Meats	meat fish or poultry	12 per cent	had none
Other vegetables	(including potatoes)	or fruit	8 per cent
Cereals or bread	whole grain or enriched	3 per cent	had none

Sharp deficiencies in dietary habits were found in income groups. Among geographic sections the South shows a greater deficiency in citrus fruits and raw greens, while the New England and Middle Atlantic area shows greatest deficiency in milk or milk products.

Tropical Medicine Foundation Seeks to Raise \$100,000—The American Foundation for Tropical Medicine, Inc., at its annual meeting in New York on January 19, approved plans to secure \$100,000 in gifts to provide for expansion of activities in the current year, including support of graduate departments of tropical medicine at American medical schools, grants for fellowships in tropical medicine, financial aid for exchange of faculty, support of technical journals in the field and support of research by grants in aid. Lieut Col Thomas T Mackie, executive officer, Division of Parasitology and Tropical Medicine, Army Medical School, Washington, D C, was elected president of the foundation. In 1942 he had been replaced as director by Dr Jean A Curran, dean and president of the Long Island College of Medicine, Brooklyn. Dr Willard C Rappleye, New York, was elected vice president, Mr William W Lancaster, New York, treasurer, and Mr Alfred R Crawford assistant to Dr Curran, secretary. An executive committee composed of Dr Curran, Dr Theodore G Klumpp, New York, Colonel Mackie, Dr Henry E Meloney, New York, Dr Rappleye, Mr Lancaster and Mr Crawford was named by the directors to serve for the current year. The directors also elected a medical committee made up of Col Charles F Craig, M C, U S Army, retired, and Ernest Carroll Faust, Ph D, New Orleans, Colonel Mackie, Dr Meloney, Dr Alfred C Reed, San Francisco, Dr George C Shattuck, Boston, and Col Joseph F Siler, M C, U S Army, retired, Washington, D C. In addition to those named, the following were elected to membership in the foundation: Gen Hugh S Cumming, U S P H S, Washington, D C; Lieut Col Albert R Dreisbach, M C, U S Army, Washington, D C; Gen George C Dunham, M C, U S Army, Washington, D C; Dr Lester J Evans, New York; Dr Edward G Huber, Newton, Mass.; Dr Edward H Hume, New York; Dr Maxwell E Lapham, New Orleans and Dr Edward I Salisbury, New York. All correspondence should be addressed to Dr Curran at 350 Henry Street, Brooklyn.

Health Advisory Council Organized—The Chamber of Commerce of the United States on February 5 announced the creation of a National Health Advisory Council to consider national health problems in relation to the war program. Dr James S McLester, professor of medicine, University of Alabama School of Medicine, Birmingham, was chosen general chairman of the council. The new council will serve to channel approved technical health information developed by the country's many scientific associations to business organizations and their members throughout the country so there may be brought about a better public understanding and appreciation of medical

science as a means of safeguarding public health to win the war. It will work through the Chamber of Commerce of the United States as a central organization which in turn will work through its membership of trade associations, chambers of commerce and corporations and firms. Membership of the council which will be increased as work progresses has been divided into three groups. Dr. Wilson G. Smillie, New York, is chairman of the community group including:

Dr. Paul D. White, Boston	Henry F. Vaughan, Dr. P. H. Ann
Dr. J. Burns Amberson, Jr., New York	Arbore represented by Nathan Sinai, D. I. H.
Dr. George W. Kosmal, New York	George R. Congell, Ph.D., New Haven, Conn.
Dr. Ernest L. Stebbins, New York	Dr. Harry Bakwin, New York
Mr. Bailey B. Burritt, New York	Dr. Felix J. Underwood, Jackson, Miss.

Dr. Leverett D. Bristol, New York, is chairman of the industrial group, comprising:

Dr. Harvey Bartle, Philadelphia	Dr. William A. Sawyer, Rochester, N. Y.
Dr. Anthony J. Lanza, Washington, D. C.	Mr. John D. Dorsett, New York
Dr. John J. Prendergast, Jr., Detroit	Philip Drinker, Ch. E., Boston
Dr. Loyal A. Shoudy, Bethlehem, Pa.	Dr. Harry E. Ungerleider, New York
	Dr. John I. Wittmer, New York
	Mr. G. W. Hardy, Chicago

Dr. James E. Paullin, Atlanta, Ga., President Elect of the American Medical Association, is chairman of the individual group, which is composed of:

Dr. Leroy U. Gardner, Saranac Lake, New York	Dr. Louis Hamman, Baltimore
Dr. George M. Piersol, Philadelphia	Dr. Wallace M. Ayer, Washington, D. C.
Dr. Russell M. Wilder, Rochester, Minn.	Miss Marion G. Howell, R. N., New York, represented by Miss Marian Sheahan
Dr. Alfred Blylock, Baltimore	Dr. Arthur F. Chase, New York
Dr. Joseph C. Doane, Philadelphia	Dr. Harold M. Marvin, New Haven, Conn.

Accidental Deaths in 1942—The National Safety Council announces that 93,000 deaths from accidents were reported in 1942 as compared with 101,513 in 1941. Of this group 27,800 were charged to motor vehicles in 1942 as against 39,969 in 1941. Accidental deaths in the home accounted for 30,500 against a similar total for 1941. Occupational accidental deaths totaled 18,500 as against 18,000 the previous year and public accidental deaths (not motor vehicle) totaled 15,500 as against 15,000 in 1941. The saving of 8,500 lives in 1942 as compared with the 1941 total is attributed entirely to a drop of 12,200 in traffic deaths accounted for largely by wartime restrictions on speed and travel. A total of 47,500 workers were killed by accidents in 1942, 18,500 on the job and 29,000 off the job. In addition nonfatal injuries to workers totaled 4,100,000 of which about 1,700,000 were caused by occupational accidents. The all-accident totals include accidental deaths of military personnel not shown separately. Motor vehicle deaths include some which also are shown in other categories, such as occupational and home. Not only was the 1942 accident toll less than for 1941 and for most recent years but the death rate of 66.4 per hundred thousand population was the lowest since 1922 when it was the same. There were 9,300,000 persons injured in accidents last year, approximately the same as in 1941, despite the decrease in deaths. One out of every 14 persons in the United States suffered a disabling injury during the year. The estimated economic loss of \$3,700,000,000 from accidents in 1942 covers both fatal and nonfatal accidents and includes wage losses, medical expense, the overhead costs of insurance and property damage from traffic accidents and fires. Children less than 5 years old were the only age group to show an increase in accidental deaths in 1942. Deaths in this group were up 2 per cent. The school child group (5 to 14 years) had a decrease of 9 per cent in fatalities. Falls brought accidental death to 24,000 persons in 1942, 4 per cent below 1941. Deaths from burns were up 17 per cent in 1942 to a total of 8,900. Even after excluding the Boston night club fire the general trend of fatalities from burns was up approximately 10 per cent. Drownings totaled 7,000, an increase of 1 per cent. As in past years, the bulk of the accident total was made up of one-death accidents. Five fatal accidents occurred in 1942 in the domestic operations of scheduled air carriers. One was in January, two in May, one in October and one in December. Passenger deaths numbered 56 and plane crew deaths 15 making a total of 71. The passenger-mile total was approximately 1,490,000,000 which indicates a passenger rate of 3.8 per hundred million passenger miles. This was 65 per cent above the 1941 rate of 2.3 and was higher than the rates for 1939 or 1938. It was lower however than the rate for any earlier year. In 1932 the rate was 15. Railroad accidents caused 4,809 deaths in the first eleven months of 1942,

excluding deaths which occurred more than twenty-four hours after the accident. This was 4 per cent more than the comparable 1941 total of 4,616.

College of Surgeons Plans War Sessions—New developments in military and civilian medical and hospital service will be brought to members of the medical profession at large and hospital representatives through a series of twenty war sessions beginning March 1, to be held throughout the United States under the sponsorship of the American College of Surgeons with the cooperation of other medical organizations and the federal medical services. Each war session will consist of an all day program lasting from 9 a. m. to 10 p. m., including luncheon and dinner conferences. There will be eight meetings in each session, four of which will be for the entire assembly and the remainder divided into two meetings each for physicians and for hospital representatives. Subjects will be similar in the different places, but some of the speakers will be changed in the different states and service commands. Nationally known representatives of the United States Army, the United States Navy, the United States Office of Civilian Defense, the United States Procurement and Assignment Service and the United States Public Health Service will address the meetings and will lead discussions in addition to participation by prominent leaders in civilian medical practice and hospital service. The schedule is as follows:

Monday, March 1	Minnesota, North Dakota and South Dakota	Lowry Hotel, St. Paul
Wednesday, March 3	Wisconsin and Illinois	Schroeder Hotel, Milwaukee
Friday, March 5	Indiana, Kentucky and Ohio	Claypool Hotel, Indianapolis
Monday, March 8	Michigan	Statler Hotel, Detroit
Wednesday, March 10	Pennsylvania and West Virginia	the William Penn, Pittsburgh
Friday, March 12	New York and Ontario	Statler Hotel, Buffalo
Monday, March 15	Massachusetts, Connecticut, Maine, New Hampshire, Rhode Island and Vermont	Statler Hotel, Boston
Wednesday, March 17	New York City, Delaware and New Jersey	St. George Hotel, Brooklyn
Friday, March 19	Virginia, District of Columbia and Maryland	John Marshall Hotel, Richmond
Monday, March 22	North Carolina and South Carolina	Charlotte Hotel, Charlotte
Wednesday, March 24	Alabama, Florida and Georgia	Tutwiler Hotel, Birmingham
Friday, March 26	Tennessee, Arkansas and Mississippi	Peabody Hotel, Memphis
Monday, March 29	Texas and Louisiana	Rice Hotel, Houston
Thursday, April 1	Kansas, Missouri and Oklahoma	President Hotel, Kansas City
Saturday, April 3	Nebraska and Iowa	Fontenelle Hotel, Omaha
Tuesday, April 6	Colorado, New Mexico and Wyoming	Cosmopolitan Hotel, Denver
Friday, April 9	Utah and Idaho	Utah Hotel, Salt Lake City
Tuesday, April 13	Southern California and Arizona	Biltmore Hotel, Los Angeles
Friday, April 16	Northern California and Nevada	Fairmont Hotel, San Francisco
Tuesday, April 20	Washington, Montana, Oregon and British Columbia	Olympic Hotel, Seattle

Dr. Irvin Abell, Louisville, Ky., chairman of the board of regents of the college in announcing the war sessions, said that although participating states and provinces for each meeting have been designated to facilitate arrangements, there will be no geographic restriction on attendance, and those who plan to attend may select the place and time which are most convenient. The American College of Surgeons canceled its 1942 national meeting and is holding in abeyance plans for a clinical congress in 1943 in the meantime offering the regional meeting plan provided by the war sessions to save the time of the doctors and other personnel and to minimize transportation difficulties without sacrificing unduly during wartime the educational and stimulative benefits of medical assemblies.

CORRECTIONS

Carcinoma of the Prostate—In the case reported on page 500 of THE JOURNAL for February 13 the total protein reported as 750 mg per hundred cubic centimeters should read 7,500 mg per hundred cubic centimeters. This very high figure, indicating the degree of "block," makes the response to orchiectomy two weeks after operation even more remarkable.

Experimental Fibroids and the Antifibromatogenic Action of Steroid Hormones—In the article by Dr. Alexander Lipschutz in THE JOURNAL, Sept. 19, 1942, "the estrogenic" (p. 172 second column line 25) should read "a gonadal" "estrogenic" (p. 174 first column lines 38 and 39) should read "masculinizing," and "fibromatogenic" (p. 175 first column, line 23) should read "antifibromatogenic."

Medical Aid to Russia

The Anglo Soviet Medical Council under the chairmanship of Sir Alfred Webb Johnson, president of the Royal College of Surgeons, has been in existence for a year. Its object is to send to Russia recent medical publications and to make Soviet work accessible here. Complete sets of the *Lancet*, *British Medical Journal*, the *Bulletins of War Medicine*, *Hygiene and Tropical Diseases*, *Proceedings of the Royal Society of Medicine*, *Journal of the Royal Army Medical Corps* and *Journal of Medical Science* have been sent. Recently *Reviews of British War Medicine*, consisting of specially written articles and translated into Russian, was presented to Mrs. Muska, wife of the Russian ambassador. Three thousand copies of it have been printed and sent to Russia. It covers a wide range of subjects, including public health, vitamin therapy, bone surgery, treatment of burns and crushes, blood grouping and the care of stored blood, hospital infections of wounds, sulfonamide and penicillin treatment, treatment of gonorrhea, bacillary and amebic dysentery, typhoid, typhus, malaria, tularemia and venereal lymphogranuloma. A volume on thoracic surgery is in preparation.

Russian articles have been received by the council, mainly through the editor of the *Soviet War News*, and have been published in English medical journals. The Society for Cultural Relations with Russia has handed over books and pamphlets for translation. An appeal was made for translators from the Russian, and replies were received from sixty-six persons, mostly doctors.

A National Collection of War Injuries

The valuable collection of pathologic specimens formed in the last great war was destroyed when the Royal College of Surgeons was bombed in 1941. At the request of the War Office and the college, the Medical Research Council has undertaken to replace it by a national collection illustrating injuries of the present war to comprise specimens, pictures, photographs and roentgenograms of lesions produced by missiles, war gas or explosion gas or by secondary missiles, such as fragments of masonry or debris, including crushing injuries, the effects of impact of blast wave in air or water and burns together with the mode of repair, the consequences of infection and the results of treatment. Without the participation of the medical officers in the services such a collection can never become comprehensive. It is hoped that they will take every possible opportunity of contributing. Specimens may be sent to Prof. M. J. Stewart Pathological Department, University of Leeds or to Professor Hadfield, Hill End Hospital, St. Albans, Herts. As the value of a specimen often depends on the care taken in collection and the preliminary treatment, a leaflet circulated by the War Wounds Committee of the Medical Research Council offering suggestions on fixation and dispatch may be obtained from the Army Medical Department of the War Office.

New Element Discovered by English Woman

Not for the first time has a woman taken part in the discovery of a new element. In 1898 salts of radium with the periodic number of 88 were prepared by M. and Mme. Curie of whom an English woman, Dr. Alice Leigh Smith, was a pupil. The wife of a British diplomat, she was the first woman in England to be awarded the degree of D.Sc. in nuclear physics. Under the auspices of the British Empire Cancer Campaign she conducted medical research from 1936 until the outbreak of war and initiated a new method of treating cancer. In July 1940 Dr. Walter Minder, director of the Radium Institute in Berne,

announced the discovery among the disintegration products of radioactive actinium, of extremely minute quantities of helvetium, periodic number 85, with properties allied to those of chlorine, bromine and iodine. The discovery was reported in the British scientific periodical *Nature*, but competent scientists expressed doubt whether the element existed on earth in nature. Subsequently Dr. Leigh-Smith, who was engaged in cancer research in Berne, observed in the behavior of radioactive reagents unaccountable irregularities which suggested the presence of some hitherto unidentified element generated on atomic disintegration. Proof of the discovery of a new element was obtained by the joint work of the two physicists at the Radium Institute, Berne. They have designated it "anglo-helvetium" to denote the collaboration of scientists of the two countries.

Medical Benefits to Natives Under British Colonial Rule

The question of the bearing of the Atlantic charter on the future of the British colonies and the effect of any international system which may arise after the war have begun to be discussed. Some recent criticisms of the government of our colonies has given rise to a vigorous defense in the House of Lords by Lord Cranborne, who has been a colonial administrator. He described the great benefits, of which the medical ones are not the least important, which our rule had brought. A comparatively small part of our empire was acquired by war and that generally at the expense of other European powers rather than directly from the natives. These colonies have been held mainly as buttresses of that sea power which had been the principal guaranty of the peace of the world. Much territory in Africa had been occupied for the campaign against the slave trade and one colony in order to make a home for slaves set free.

Describing medical benefits he said that in Malaya in the last thirty-five years we reduced the death rate from 46 to 20 per thousand. We set up there hospitals and welfare centers. We introduced compulsory education for all Malay boys between the ages of 7 and 14 years. We developed the great rubber industries to the benefit not only of ourselves but of the natives and of the world. We transformed the island of Singapore from an unproductive stricken jungle into one of the great ports of the world.

We established medical schools in East and West Africa, Ceylon, Malta and Fiji, which turned out physicians. Nurses and medical auxiliaries also were trained. Important investigations were carried out by our own organizations and by the Rockefeller Foundation. Slowly but steadily the problems of malaria, yellow fever, venereal disease, malnutrition and tuberculosis were being tackled. In remote unhealthy fever-ridden districts members of the colonial medical service were giving their lives for the welfare of the native population. We also promoted social security and established satisfactory labor conditions.

Control of Rubber Gloves

For the year 1943 the maximum number of pairs of rubber gloves obtainable by physicians is six, by midwives six, by district nurses not practicing as midwives four and by nurses in private practice two. Physicians can apply for supplementary rations but must give satisfactory reasons. These regulations do not apply to gloves required for work done in hospital, nursing homes or other institutions or done in extra-domiciliary practice on the behalf of such institutions.

The Diagnosis and Treatment of Tuberculosis

The minister of health has had under consideration the question of improved arrangements for improved treatment and early diagnosis of tuberculosis. He has issued a circular to the local health authorities pointing out the importance of providing means for miniature radiography for which transportable equipment will be allocated to them. Arrangements are also

being made by the Ministry of Health for training the necessary staff for operating this new means of diagnosis. Its importance requires that the arrangements for miniature radiography should be standardized.

Financial assistance is to be made available to all persons who suffer loss or diminution of income while undergoing treatment for pulmonary tuberculosis, whether in an institution or at home and who have one or more persons wholly or mainly dependent on them.

Antidiphtheria Drive

The Ministry of Health is making a drive to get as many children as possible inoculated against diphtheria. In 685 out of 1,440 local health districts it is reported that 50 per cent or more of the children between the ages of 5 and 15 years have been inoculated. The same result has been achieved for children aged 1 to 5 years in 247 districts. In 80 districts a percentage of 90 or more was attained.

Russell John Howard

The death of Russell John Howard has removed a well known surgeon and teacher. Born in 1875 he entered the London Hospital as a student in 1895 and graduated M.B. Lond. with first class honors and a gold medal. Adopting surgery, he took the M.S. with a gold medal and the F.R.C.S. in 1903. In 1908 he was appointed assistant surgeon to the London Hospital. There he became famous for his incisive style of teaching. 'What is wrong with this patient?' he would say. When a student began 'Well sir it might be—' Russell would reply 'I didn't ask you what it might be. Surely you can have an opinion. I used to be wrong nine times out of ten. Now I'm wrong only seven times out of ten.' He wrote a number of successful textbooks: 'Practice of Surgery,' 'Surgical Nursing,' 'Surgical Emergencies' and 'House Surgeon's Vade Mecum.' Because of his teaching gifts he was described as an 'institution' of the London Hospital, where he exercised a profound influence on many generations of students. After his retirement as surgeon to the hospital under the age limit he continued to lecture on surgery and surgical nursing.

BUENOS AIRES

(From Our Regular Correspondent)

Dec. 25, 1942

Aviators' Sickness

In a lecture recently delivered at the National Academy of Medicine of Buenos Aires, Dr. Rene Crouchet discussed the psychologic phenomena of aviators' sickness which are brought about by physiologic phenomena due to the variations of air pressure and of the amount of oxygen in the air, as well as by velocity and rapid acceleration. The body tolerates velocities of acceleration of from 6 to 14 g and even 17 g if acceleration is of short duration (from two to ten seconds). Prolonged velocity, poor hygienic practices, fatigue, overwork and intoxication are the causes of grave disorders. The use of sulfonamide compounds is prohibited. Tonics, especially vitamin A, are indicated to prevent and control physical fatigue and certain visual disorders.

Infant Mortality in Colombia

The infant mortality rate in Colombia is high. Death occurs from nutritional disorders the result of insufficient or improper feeding even in infants of large cities. The figures of infant mortality during the first year of life were as follows: 38,561 deaths (30.5 per cent) in 1935, 37,839 in 1936, 39,418 in 1937, 43,809 in 1938, 45,523 in 1939 and 40,956 in 1940. The rate of mortality for children between the ages of 1 and 10 years was as follows: 24,489 children in 1935, 29,648 in 1940 and of figures ranging between the foregoing in the years from 1936 to 1939 with the exception of 1938, when the greatest rate of mortality was observed that is 37,013 deaths.

Society Reunions

The second annual reunion of the Argentine Medical Association took place in Cordoba on the first week of December 1942. The speakers were Drs. Raul F. Vaccarezza, Andres R. Arena, Gonzalo Bosch and Jose Belbey. Official topics discussed were "Tuberculosis of Bovine Origin," "Care of the Insane" and "Medical Charlatanism."—The first Cardiology Week was recently held in the National Academy of Medicine of Buenos Aires. The main topic of discussion was "Cardiac Insufficiency."

Prize for Research Work

The Rodolfo Fitte Foundation established a prize of 10,000 Argentine pesos (\$2,500) for the best work on acute anterior poliomyelitis which is presented between January and December 1943. Argentine and Pan American investigators may enter the contest, details of which can be obtained from the president of the Rodolfo Fitte Foundation, Avenida Quinteros 39, Buenos Aires.

Medical Societies

The Argentine Society of Proctology of Buenos Aires was recently established. Dr. Carlos Bonarino Urdondo is the president. The society aims to reunite Argentine proctologists in a specialized group and also to organize a Pan American Society of Proctology and to create postgraduate courses of proctology as a specialty.

Personals

Dr. Leo Eloesser, professor of clinical surgery, Stanford University School of Medicine, accepted the invitation of the Argentine medical profession through Dr. Oscar Ivanisevich, dean of the Instituto de Clinica Quirurgica of Buenos Aires, and visited Argentina. He delivered several lectures before the Argentine Medical Association and other medical and surgical societies of Buenos Aires. In some of the lectures the speaker discussed "Treatment of War Fractures."

Dr. Jose Arce recently returned home from the United States where he carried on important studies on organization and functions of blood banks. He will report in detail his observations to our government and will show the advisability of organizing blood banks in the various provinces of Argentina, at least one bank in every province.

Deaths

Dr. Jose J. Puente of Buenos Aires, a syphilologist and specialist in venereal diseases and the head of the Department for Prevention of Leprosy, Syphilis and Venereal Diseases of the National Department of Hygiene, recently died in that city.

Marriages

HOWARD W. SMITH, Woodward, Iowa, to Miss Madeline Rue of Bismarck, N. D., in Des Moines, December 25.

ROBERT CANTRELL FEAMSTER, San Antonio, Texas, to Miss Helen Louise Greer of New Orleans, November 28.

CAREY ADDISON STONE, JR., Crewe, Va., to Miss Cornelia Daniel Preston of Lewisburg, W. Va., January 7.

LE ROY F. CATTERSON, Oskaloosa, Iowa, to Miss Lucile Tindle of Malcom in Montezuma, December 13.

CHARLES JAMES FRANKEL, University, Va., to Miss Gladys Louise Birmingham of Buena Vista, January 8.

CHARLES HAMILTON REID, JR., Winston-Salem, N. C., to Miss Elizabeth Ray of Chapel Hill, recently.

WILLIAM E. MORROW, Chicago, to Miss Margaret R. Leonard of Monmouth, Ill., December 31.

CLARA Z. JOEL, Richmond, Va., to Corporal Edward Fleisher of Bethlehem, Pa., January 5.

GEORGE R. CRISLER, Winter Park, Fla., to Mrs. Jane Bacher in Miami, recently.

Deaths

Wilmer Krusen * Media, Pa., Jefferson Medical College of Philadelphia, 1893, president of the Philadelphia College of Pharmacy and Science from 1927 to March 31, 1941, when he retired with the title of president emeritus, in 1902 became professor of gynecology and later emeritus professor of gynecology at the Temple University School of Medicine, in 1913 he was elected a trustee, in 1914 vice president and in 1927 honorary vice president of the university, director of public health from 1916 to 1920 and again from 1924 to 1928, member of the House of Delegates of the American Medical Association in 1917, 1918, 1919 and 1921, served as president of the Medical Club of Philadelphia, the Philadelphia Obstetrical Society, the Philadelphia Clinical Association and a member of the Philadelphia Rotary Club, was director of the Philadelphia Chamber of Commerce, a trustee of the Welfare Federation and a member of the board of county prison inspectors, had been director and vice president of the Public Charities Association of Pennsylvania, a member of the College of Physicians of Philadelphia, a fellow of the American College of Surgeons, served as gynecologist at the Samaritan and Garretson hospitals, a member of the board of trustees of the Philadelphia State Hospital, associated with the Jefferson, Temple University, City, Philadelphia General and Municipal hospitals, formerly a member of the advisory council of the Henry Phipps Institute, in 1916 received the honorary degree of doctor of laws from the University of Pittsburgh, the honorary degree of doctor of science was awarded to him by Temple University in 1927 and by Franklin and Marshall College, Lancaster, Pa., in 1933, in 1934 received the honorary degree of master of arts in medicine from the Hahnemann Medical College and Hospital, aged 73, died, February 9, of coronary infarction.

Lee Hollister Ferguson * Cleveland, Columbia University College of Physicians and Surgeons, New York, 1917, director of student health service at Western Reserve University, where he was formerly demonstrator and clinical instructor in medicine, instructor in medicine at his alma mater from 1918 to 1920, research assistant department of preventive medicine and hygiene, Harvard University, Boston, 1920-1921, had for several years been assistant supervisor of health education in the public schools of Cleveland, member of the National Tuberculosis Association, the Anti-Tuberculosis Association of Cuyahoga County, the American Association of College Health Services and the Cleveland Academy of Medicine, fellow of the American Public Health Association, a member of the board of trustees of the Cleveland Child Health Association, aged 57, died January 27, in the Leonard C. Hanna House, University Hospitals, of Hodgkin's disease with terminal pneumonia.

Frank E. Detling * Los Angeles, Northwestern University Medical School, Chicago, 1901, associate clinical professor of surgery, University of Southern California School of Medicine, specialist certified by the American Board of Otolaryngology, member of the American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Oto-Ophthalmological Society, fellow of the American College of Surgeons, past president of the Los Angeles Eye and Ear Society and chairman of the eye and ear section of the California Medical Association, formerly otolaryngologist to the Graves Dispensary, attending and consulting otolaryngologist to the Children's Hospital and for many years senior otolaryngologist to the Los Angeles County Hospital, aged 66, died, December 25, of carcinoma of the stomach.

Charles Briggs Crittenden, Louisville, Ky., Vanderbilt University School of Medicine, Nashville, Tenn., 1912, member of the Kentucky State Medical Association, served as director of the division of maternal and child hygiene of the state department of health of Kentucky, formerly registrar of vital statistics and commissioner of the department of public health of Tennessee, formerly health commissioner of Chattanooga, Tenn., and Wilkes-Barre, Pa., had been health director of rural study of the American Public Health Association, past president of the Pennsylvania Public Health Association, at one time director of the Kirby Memorial Health Center, Wilkes-Barre, aged 54, died, January 15, of coronary occlusion.

Donald Da Costa Shira, La Rue, Ohio, Ohio State University College of Medicine, Columbus, 1914, member of the Ohio State Medical Association, during World War I served as a captain in the medical corps of the U. S. Army, served as health commissioner for Summit County from 1920 to 1922 and as director of health for the city of Akron from 1922 to 1927, at one time had been assistant secretary and medical

adviser of the Ohio Public Health Association, for many years medical editor of *Ohio Public Health*, aged 55, died, December 30, of coronary occlusion.

Arthur Kehew Day, Concord, N. H., Harvard Medical School, Boston, 1889, member of the New Hampshire Medical Society which in 1940 awarded him a fifty year membership gold medal, during the Spanish-American War served in the U. S. Army as a first lieutenant and assistant surgeon, for a number of years was school physician of Concord, for twenty-five years served as attending physician at the Margaret Pillsbury General Hospital, formerly U. S. Pension Examining Surgeon for Merrimack County, aged 80, died, December 31, of coronary thrombosis.

Charles Louis Ahner, Chicago, Bennett Medical College, Chicago, 1913, member of the Illinois State Medical Society, aged 75, died, January 10, in Kenilworth, Ill., of arteriosclerosis and myocarditis.

Theophilus Powell Allen * New York, Columbia University College of Physicians and Surgeons, New York, 1923, member of the National Gastroenterological Association, served during World War I, aged 46, associate attending physician, department of medicine, St. Luke's Hospital, where he died, January 27, of rheumatic heart disease.

David Tarwater Austin, Sarasota, Fla., Memphis (Tenn.) Hospital Medical College, 1911, captain in the medical reserve corps of the U. S. Army, not on active duty, served overseas during World War I, aged 65, died, December 31, of myocarditis.

Alexander Aloysius Backiel, Chicago Heights, Ill., Chicago Medical School, 1928, member of the Illinois State Medical Society, aged 43, on the staff of the Southtown Hospital, Chicago, where he died, February 1, of transverse myelitis.

Hinton Miller Belflower, Sycamore, Ga., Atlanta College of Physicians and Surgeons, 1911, member of the Medical Association of Georgia, served as a member of the county board of education, aged 65, died, December 3, of cerebral hemorrhage.

Arthur Birt, Halifax, N. S. Canada, M.B., C.M. 1887 and M.D. 1898, University of Edinburgh Faculty of Medicine, Scotland, spent his earlier years of practice on the staff of an English mental hospital and as a ship's surgeon, died, November 19, in Wolfville of chronic subdural hematoma.

James R. Boring, Canton, Ga., Atlanta College of Physicians and Surgeons, 1899, member of the Medical Association of Georgia, had recently been an examiner for the Cherokee County Selective Service System and served in the same capacity for the draft board during World War I for twelve years served on the board of education of Canton, aged 64, died recently of acute coronary occlusion.

Clemens Bossard, Wauwatosa, Wis., Hahnemann Medical College and Hospital, Chicago, 1885, aged 80, died, January 6, of coronary disease.

John Hammond Bradshaw, Orange, N. J., College of Physicians and Surgeons, New York, 1884, member of the Medical Society of New Jersey, fellow of the American College of Surgeons, consulting surgeon to the Orange Memorial Hospital, Orange, and the Jersey City Hospital, Jersey City, in 1941 the Essex County Medical Society presented him with a scroll of appreciation for practicing medicine for fifty years or more, aged 82, was found dead, January 20, of illuminating gas poisoning, self administered.

William Branower * New York, Columbia University College of Physicians and Surgeons, New York, 1904, specialist certified by the American Board of Anesthesiology, Inc., member and in 1917 president of the American Society of Anesthetists, Inc., member of the American Association for Thoracic Surgery, aged 61, attending anesthesiologist to the Mount Sinai Hospital, where he died, January 17, of coronary thrombosis.

William Charles Bristow * Emhouse, Texas (licensed in Texas by years of practice), past president of the Navarro County Medical Society, aged 68, died, January 6, in the Navarro Clinic Hospital, Corsicana, of heart disease.

Ruth Gudrun Brogger, Orange, N. J., Syracuse University College of Medicine, 1941, served as an intern at the Syracuse University Medical Center, aged 34, died, December 28, in the Hospital of St. Barnabas and for Women and Children, Newark, of acute leukemia.

George Edwin Brown, Hackensack, N. J., College of Physicians and Surgeons, New York, 1875, formerly physician for the county's penal institutions and for the city board of health, aged 90, died, December 31, of arteriosclerosis.

Lewis Allen Buchman * Canton, Ohio, University of Wooster Medical Department, Cleveland, 1903, for many years

chief of surgery at the Aultman Hospital, where he was president of the medical staff in 1939, served also as lecturer in the hospital's school of nursing, past president of the Canton Medical Society, fellow of the American College of Surgeons served as a captain in the medical corps of the U S Army during World War I, aged 67, died, January 6 of Parkinson's disease

Lyman Ambrose Burnside, Marshall, Ill College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1905, served during World War I at one time associated with the U S Public Health Service and the Veterans Administration aged 63, died recently in Biloxi Miss of heart disease

Noah Arthur Burr, Higganum Conn, Yale University School of Medicine New Haven, 1901 member of the Connecticut State Medical Society, at one time school physician in Manchester formerly health officer of Haddam, aged 67, died January 9, of cerebral hemorrhage

Benjamin Charles Deeley, Pasadena, Calif, University of Wooster Medical Department Cleveland 1908 member of the Ohio State Medical Association aged 58, died, November 29, of cerebral hemorrhage due to arteriosclerosis

James Lawrence Devlin, New York Queens University Faculty of Medicine, Kingston Ont, Canada 1899 member of the Medical Society of the State of New York formerly chief examiner of lunacy in New York City member on the staff of the Murray Hill Hospital served as physician for the Richmond County Jail, aged 65, died, January 11 in the Muhlenberg Hospital, Plainfield, N J, of coronary thrombosis

Joseph Francis Duane @ Peoria Ill Rush Medical College Chicago 1903 member and at one time vice president of the American Academy of Ophthalmology and Otolaryngology member of the staff of St Francis Hospital, aged 62 died January 21, of primary diffuse generalized amyloidosis

Marion Alexander Duncan, Chanute Kan Medical College of Indiana, Indianapolis 1891, aged 87, died, January 10, of cerebral hemorrhage

Frank Hamilton Dunklin, Gallatin, Tenn University of Tennessee Medical Department Nashville 1886 aged 79, died January 2, of heart disease and chronic nephritis

Darius Edrington, Avery, Texas Memphis (Tenn) Hospital Medical College 1906 member of the State Medical Association of Texas served as a first lieutenant in the medical corps of the U S Army at Camp Lee, Virginia, during World War I for twenty years served as president of the school board aged 60 died November 20 of cridorenal hypertensive disease

Moosha Berkowitz Freid, New Rochelle, N Y University of the City of New York Medical Department, 1895 member of the Medical Society of the State of New York, at one time attending physician at the Lebanon Hospital New York, aged 78, died January 21, of carcinoma of the intestine

Sheridan C Griffith Worthington, Ohio National Normal University College of Medicine Lebanon 1893 aged 76 died, January 8, in the Starling Loving University Hospital, Columbus of uremia

Francis Royal Hendricks @ Ventura Calif, Jefferson Medical College of Philadelphia 1924, served as physician for the Associated Oil Company in Ventura aged 44 chief of the Foster Memorial Hospital, where he died, December 27, of coronary thrombosis

Retta Gifford Kilborn, Toronto Ont, Canada Trinity Medical College Toronto, 1891, for many years served as a medical missionary to China under the Women's Mission Board of the Methodist Church professor emeritus of pediatrics in the faculty of medicine West China Union University, and superintendent of the Hospital for Women and Children in Chengtu Szechwan, China aged 78 died December 1

Thomas Jackson Pennington, Nacogdoches, Texas, National University of Arts and Sciences Medical Department, St Louis 1917 member of the State Medical Association of Texas, county health officer on the staff of the City Memorial Hospital aged 57, died suddenly, December 26, of heart disease

John Thomas Phillips, Long Beach Calif, Rush Medical College, Chicago, 1897 formerly local physician for the Great Northern Railroad, and president of the Security State Bank at Newport Wash aged 71 died December 6 of carcinoma

Francis Marion Pitts, Des Moines Iowa Keokuk Medical College 1891, aged 75 died December 21 of diabetes mellitus

Frederick Judd Rathbun @ New Windsor, Ill Rush Medical College Chicago 1913, aged 55 died, January 29

in the Galesburg (Ill) Hospital of cerebral hemorrhage and arteriosclerosis

Charles John Reynolds, Buffalo, Niagara University Medical Department Buffalo, 1890, member of the American Society of Anesthetists, Inc aged 77, served on the staff of the Millard Fillmore Hospital, where he died, January 11, of carcinoma of the liver

Benjamin Travis Robinson, New Augusta, Miss, Medical Department of Tulane University of Louisiana, New Orleans, 1906, member of the Mississippi State Medical Association, from 1926 to 1932 director of the Perry County Health Department and part time health officer from 1932 to 1938 served during World War I president of the South Mississippi Medical Society in 1940, aged 63 died, December 2, of a cerebral hemorrhage

Linn L Roebuck @ Marion Ohio, Starling Medical College Columbus, 1894, on the staff of the Marion City Hospital, aged 69 died January 14, of coronary thrombosis

Frank Charles Sarazin @ Superior, Wis, Chicago Medical College 1888 on the staffs of St Mary's and St Francis hospitals aged 76 died, December 17, of coronary thrombosis

Martin John Sauter, Newport, Ky Eclectic Medical College Cincinnati 1916, member of the Kentucky State Medical Association served as coroner of Campbell County for many years served during World War I, aged 50, died, January 2 in Lakewood Ohio of coronary disease

James M Talcott, Omaha, State University of Iowa College of Medicine, Iowa City, 1896, served as chief probation and parole officer for the federal government for eight years at one time located at Crofton Neb, and in 1909 was elected to the state legislature and remained as representative from his district for several years aged 70, died, November 19, of heart disease

James Richard Tarrant, Birmingham Ala, Medical College of Alabama, Mobile 1887 aged 81, died, December 16 of coronary occlusion and generalized sclerosis

William Franklin Temple, Boston, Harvard Medical School Boston, 1911 member of the Massachusetts Medical Society, past president of the Boston Society of Anesthetists, served on the staff of the Massachusetts Women's Hospital aged 55 died December 25, at his home in East Pembroke of an acute kidney obstruction

Edward K Wolfe, Pilsen Wash, Physio Medical College of Indiana Indianapolis 1898 past president of the Whitman County Medical Society, for many years health officer aged 72 died December 4, in St Ignatius Hospital, Colfax of uremia and diverticulitis of the colon

DIED WHILE IN MILITARY SERVICE

Pashupati Joseph Sarma @ Chicago Hahnemann Medical College and Hospital Chicago 1916, served as associate professor of surgery at the University of Illinois College of Medicine formerly associate in surgery at the Loyola University School of Medicine, where he was instructor from 1927 to 1929 and assistant in surgery from 1924 to 1927 specialist certified by the American Board of Surgery fellow of the American College of Surgeons, on the staffs of the Ravenswood and Cook County hospitals served during World War I was called to active duty March 10 1941 as chief of the surgical service at the Station Hospital, Camp Berkeley, Texas with rank of lieutenant colonel and later was promoted to the rank of colonel in the medical corps of the Army of the United States aged 49 died, January 21, in Fort Sam Houston, Texas, of coronary arteriosclerosis

Benjamin R Roman @ New York University and Bellevue Hospital Medical College, New York, 1929, specialist certified by the American Board of Pediatrics, Inc, on the staffs of the Park West Hospital and the New York Polyclinic Medical School and Hospital, began active duty as a captain in the medical corps of the Army of the United States Nov 9, 1942 aged 37 died January 16, at Modesto Calif, in an automobile accident

Henry Fischer Standerwick Jr, New York, Columbia University College of Physicians and Surgeons, New York, 1940 in August 1942 began active duty as a first lieutenant in the medical corps of the Army of the United States attached to Company B, 81st Armored Medical Battalion 11th Armored Division, Camp Polk La, where he died, January 5, of encephalitis aged 28

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act and in cases in which they refer to drugs and devices they are designated D D N J and foods, F N J. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

El Panel Cuban Honey—Albert H. Hoffman trading as Hoffman Health Products Tampa, Fla. Shipped Oct. 14, 1939. Composition ordinary honey. Misbranded because of false representations on label that this was a "wonder honey" in that it differed materially from ordinary honey, that it contained minerals that would help build bones, muscle and tissue, materially in excess of the amount of such minerals in ordinary honey, that it would supply the elements valuable in ailments resulting from mineral deficiencies in amounts materially in excess of those contained in ordinary honey, that it possessed proportionately high amounts of potassium, sodium, calcium, magnesium, iron, phosphorus, chlorine, sulfur, silicon and undetermined minerals that it had value as a food, body builder and constructive nutritional factor, materially in excess of that found in ordinary honey, and that it contained minerals and other nutritional elements lacking in other honeys, whereas it did not differ materially from the ordinary product. Further misbranded because of false and misleading label statements that it possessed efficacy as a dietary supplement in the treatment of sinus, coughs, asthma, hay fever, constipation, stomach ulcers and digestive elements and as a general tonic and body builder, that it had natural healing properties, was of greater value to both children and adults who are anemic, have poor appetite and other symptoms of run-down condition, that it would alkalize, vitalize and uphold the body and in preventing respiratory ailments and build resistance would help remove mucus and be a boon to raw and inflamed respiratory tracts, that it would benefit bowel and colon trouble by helping to change the intestinal flora, that it contained a pollen which would counteract the pollen which causes hay fever, that it would benefit stomach disorders such as ulcers and among other things would be a tonic, body builder and weight increaser.—[D D N J F D C 483 September 1942]

Hahn Becomx Capsules—International Vitamin Corporation, Brooklyn. Shipped Dec. 9, 1940. Adulterated because strength differed from and quality fell below that which it was represented to possess, namely, "each capsule contains B₁—100 International (200 Sherman) Units" whereas it contained not more than 60 U. S. P. units of vitamin B₁ per capsule (or an equal amount of international units). Misbranded for the same reason. Product was also charged to be adulterated and misbranded under the provisions of the law applicable to foods as reported in F N J No. 2821.—[D D N J F D C 476 September 1942]

Klorseptie Oil—Howard D. Dry trading as High Chemical Company, Philadelphia. Shipped between Jan. 12 and Feb. 14, 1940. Composition essentially a semiviscous oil having the odor of eucalyptus and containing an organic chloride but no free chlorine. Misbranded because label statement "Klorseptie Oil is a chlorinated topical dressing" containing approximately 25% chlorine was misleading since product contained no free chlorine. Further misbranded because of false and misleading label claim "Useful as a topical dressing in burns, infected wounds, both superficial and deep, Otitis Media and skin lesions" since the product would not be efficacious for such purposes.—[D D N J F D C 468 September 1942]

Klorseptie Ointment—Howard D. Dry trading as High Chemical Company, Philadelphia. Shipped between Jan. 12 and Feb. 14, 1940. Composition an amber-colored salve with a eucalyptus odor but no free chlorine. Misbranded because label falsely represented that it would be useful in treating wounds, lacerations, abrasions, burns and wherever a topical dressing is indicated.—[D D N J F D C 468 September 1942]

Kurex Diabetic Tonic—Richard F. Hillgrove and Walter P. Weihe trading as Curex Hillgrove Laboratories, Inc., Cincinnati. Shipped Sept. 26, 1940. Composition essentially water, alcohol, reducing sugars and plant extracts including emodin-bearing drugs and a trace of unidentified alkaloïds. Misbranded because label did not bear common or usual name of each active ingredient and kind, quantity and proportion of alcohol. Further misbranded because of label representations that it would be efficacious in treating diabetes, enable a diabetic patient to eliminate the taking of insulin, was helpful in the treatment of blindness caused by diabetes, would heal ulcerated feet and legs caused by diabetes, would

be efficacious in treating run-down conditions and other ailments contracted by poor living circumstances, was a systemic tonic and would be efficacious in the treatment of many ailments common to bad blood and other conditions such as rheumatism and those caused by kidney disorders and would restore to appetite and improve the nervous condition and general health.—[D D N J F D C 485 September 1942]

Lawrence Mack's Laxrid—Lawrence Mack, Inc., Detroit. Shipped Jan. 6, 1941. Composition essentially epsom salt, Glauber's salt, sodium bicarbonate, tartaric acid, citric acid and small amounts of sodium phosphate, potassium and sodium chlorides, saccharin and peppermint oil. Misbranded because directions for use on label were not suitable for a laxative and because claim on package and in circular of report of alleged laboratory test to the effect that examination had shown the product to be entirely free from any of the poisonous and harmful substances listed below gave the false impression that the product contained nothing deleterious. Further misbranded because statements in accompanying booklet entitled "How I Reduced" represented that use of Laxrid would "do away with excess weight," effect permanent reduction, relieve constipation, remove heaviness of body and bloated, sluggish feeling, relieve gas and acids and enable the user to get up full of vim, vigor and vitality.—[D D N J F D C 447 September 1942]

Mineralvita—Mineralvita Sales Company, Toledo, Ohio. Shipped between Feb. 1 and 3, 1941. Composition essentially sodium sulfate (1.3 per cent) and slaked lime (0.9 per cent) with only inconsequential traces of if any manganese, peptonate, lithium, carbonate, calcium, phosphate, niangnese sulfate, dipotassium phosphate, diodium phosphate, lithium bromide, magnesium glycerophosphate, ferric phosphate and magnesium chloride. Adulterated because label falsely represented that the minerals in the latter group were present in consequential amounts and that if the product were taken in the recommended dosage in connection with regular meals it would furnish young and old their daily requirement of minerals and that Mineralvita had been scientifically blended with the minerals found in the human system and then treated by a form of electrolysis which prepared them for assimilation into the blood stream. Misbranded for the foregoing reasons and because label claim as to mentioned minerals treated by electrolysis was false and misleading since it did not reveal that any treatment by electrolysis to which the water may have been subjected had not affected its composition or quality in any manner. Further misbranded because name "Mineralvita" and statement on shipping case label "Manufactured from nature's minerals to promote health and strength" were false and misleading since the product did not contain life minerals, was not manufactured from natural minerals and could not be depended on to promote health and strength.—[D D N J F D C 472 September 1942]

Nu Vig Or Laxative Tonic—W. B. Goebel trading as Botanical Medicine Company, Kalamazoo, Mich. Shipped between June 7 and 10, 1940. Composition plant material including cloves, capicum, an emodin-bearing drug such as senna and a bitter principle such as gentian, with sulfur, sodium sulfate, magnesium carbonate and sodium bicarbonate. Misbranded because the label claim that the product was a tonic was false and misleading in representing that this mixture would restore vigor and supply new vigor.—[D D N J F D C 426 September 1942]

Pelrodine—Howard D. Dry trading as High Chemical Company, Philadelphia. Prepared only by Iodine Products Co., Philadelphia, Pa. Shipped between Jan. 12 and Feb. 14, 1940. Composition only one ingredient reported, 0.09 grain of elementary iodine per fluid ounce, whereas label declared presence of 0.2 grain of this substance, hence misbranded. Adulterated because strength differed from and quality or purity fell below the amount of elementary iodine represented on the label.—[D D N J F D C 468 September 1942]

R M Dietary Supplements Vitamin A and D—River Mouser, Los Angeles. Shipped Nov. 2, 1940. Adulterated because its strength differed from and its quality fell below that which it was represented to possess, namely, 3,140 international units of vitamin A and 314 international units of vitamin D per tablet, whereas it contained not more than respectively only 30 and 150 international units of these vitamins. Misbranded for the same reason. Further misbranded because container was so filled as to be misleading. Also misbranded and adulterated under provisions of the law applicable to foods as reported in F N J No. 2549.—[D D N J F D C 477 September 1942]

Rux Compound (Regular and Strengthened)—Williams S. L. K. Laboratories, Milwaukee. Shipped July 26, 1940. Composition "Regular" —essentially sodium potassium and strontium salts of salicylic, benzoic and acetic acid, and extracts of plant drugs including quinine with saccharin and water, the total amount of salicylic acid being 21.1 grams per fluid ounce. Strengthened —essentially the same ingredients, salicylic acid being present in the amount of 32.8 grams per fluid ounce. The compounds were misbranded because of false label representations for their efficacy for pronounced pain and for relief of muscular pain and congestion.—[D D N J F D C 454 September 1942]

Vi An Tablets—Vegetates, Inc., Los Angeles. Shipped Nov. 29, 1940. Adulterated because its strength differed from and quality fell below that which it was represented to possess, namely, 1250 international units of vitamin A and 125 international units of vitamin D, whereas biologic assay showed that they contained respectively only 40 and 60 units of these vitamins. Misbranded because of false and misleading label statement "Four tablets a day furnish 5,000 I. U. Vitamin D, 500 I. U. Vitamin A" and adulterated under the provisions of the law applicable to food as reported in F N J No. 2822.—[D D N J F D C 478 September 1942]

Correspondence

POSTOPERATIVE PULMONARY EMBOLISM AFTER THIGH AMPUTATION

To the Editor—The statistics published by Veal in the January 23 issue of *THE JOURNAL* relative to the frequency of pulmonary embolism following thigh amputations are enhanced in value by comparison with the results of other workers in this field.

Over a period of fourteen years I have either personally performed or supervised 132 supracondylar amputations of the thigh, 32 for arteriosclerotic gangrene, 81 for diabetic gangrene, 9 for embolic gangrene and 4 for thromboangitis obliterans. Of this group there have been seven sudden deaths either within forty-eight hours following operation or within a week, a percentage of 5. In none of these cases was ligation of the femoral vein performed. This is in strong contrast to Veal's percentage of 42.1 without ligation and 17.5 with ligation. Of the seven deaths in my series, the diagnosis between coronary artery thrombosis and pulmonary embolism was not clearcut nor was the diagnosis made at autopsy.

It is my belief that postoperative pulmonary embolism in thigh amputations can be minimized by getting the patient out of bed as soon after the operation as feasible. In my cases the very next day is usually the time for getting these patients up in a wheel chair. I believe also that the avoidance of the use of a tourniquet in the performance of the operation is another factor in preventing postoperative embolism.

SAUL S. SAMUELS, M.D., New York

CONTINUOUS CAUDAL ANALGESIA IN OBSTETRICS

To the Editor—Any advancement in the field of childbirth pain relief is highly welcomed and should receive prompt and due recognition. There are sufficient disadvantages and contraindications to the method, as indicated in the article of Gready and Hesseltine (*THE JOURNAL*, January 23). To those listed by them can be added the following, several of which have been observed in our clinic at Indiana University. It is exclusively a hospital procedure and therefore restricted to 60 per cent of laboring women. The necessity for a competent attendant further restricts the use of the method. The method is rather technical—at least the insertion of the caudal needle must be done by one specially trained—either the obstetrician or a resident. There is an undesirably high percentage of failures. Hingson and Edwards report 11 per cent necessitating discontinuance of the method or supplementing other anesthesia. Such contraindications as hypotension, hypertension, placenta previa, local infection about the hiatus, hysteria and apprehensiveness are to be observed.

The use of a nylon ureteral catheter as employed by Manalan appears to afford certain advantages over the use of the needle. It is less likely to break, it eliminates the danger of piercing the dura. It can be passed higher if the curve of the sacral canal is exaggerated and it allows the patient more freedom in turning and lying on the back (Manalan, S. A. Caudal Block Anesthesia in Obstetrics, *Indiana M. J.* 35:564 [Oct.] 1942). There is a risk of vasomotor or shock reaction (Gready and Hesseltine, page 229, report such an accident in a case of hypertensive toxemia). The bladder urge is lost, urine escapes during contractions from pressure of the advancing part or has to be removed by catheter.

In all fairness, despite these objections, the several important advantages of continuous caudal analgesia should be enumerated. Labor is painless and comfortable, the patient feeling sufficiently

at ease to enjoy reading and normal sleep. The patient retains all her faculties and has a normal toleration for fluids and food both during and immediately after labor. The method may be employed throughout labor. Labor is shortened. The method provides ideal safety for the infant, particularly the premature (narcotics and sedatives are eliminated, and the need for resuscitation is greatly minimized, probably the most important contribution of the method). There is unusual relaxation of the perineal musculature, lessening resistance to the advancing head and facilitating forceps delivery and breech extraction. There is no need for supplementary anesthesia for manual delivery or repair work. Uterine bleeding is diminished. Molding of the fetal head is almost negligible. Postdelivery complications appear to be reduced. At laparotomy the peritoneum is desensitized.

As long as a method of analgesia is applicable only to the minority of laboring women (those in hospitals having competent attendants) and must be administered by specially trained individuals, that method cannot be accepted as "the last word in obstetric analgesia."

This expression has been prompted in behalf of the average woman laboring in an average hospital and attended by an average attendant. It is predictable that the use of caudal analgesia as an obstetric relief will be limited eventually to selected cases conducted by extra competent hands.

C. O. McCORMICK, M.D., Indianapolis

SINUS BRADYCARDIA

To the Editor—Relative to the significant communication on sinus bradycardia by Dr. Paul D. White (*THE JOURNAL*, Oct. 24, 1942, p. 642) it may be of interest to report briefly my experiences in the examinations of approximately 36,000 men aged 18 to 45 at this station.

Sinus bradycardia below 50 was observed in relatively few instances. A rate of 44 was the lowest noted, occurring in 2 men. I was an athlete (professional boxer), the other was not. The majority of the examinees exhibiting sinus bradycardia below 50 were either athletes or men engaged in strenuous activity. Many well known athletes examined at this station, including Al Hostak, former World's middleweight boxing champion, George Athlans, Olympic diver from Canada, and college football players, revealed no sinus bradycardia. The absence of sinus bradycardia under 40 in 36,000 consecutive men would seem to indicate that sinus bradycardia of such pronounced degree is a rarity. However, it is possible that the nervous tension resulting from the induction examination was in part responsible for the absence in our examinees of the extreme degrees of sinus bradycardia to which White has drawn attention.

MORRIS WILBURNE, First Lieutenant, M. C., A. U. S.
Cardiologist, Examining Board, U. S. Army Examination and Induction Station, Tacoma, Wash.

"OCHRONOSIS OF THE SCLERA"

To the Editor—I should like to call attention to the discussion of an article on page 1282 in the Dec. 19, 1942 issue entitled "Ochronosis of the Sclera and Cornea Complicating Alkaptonuria. The Literature, Report of Four Cases." In closing the discussion Dr. Smith stated that "Sealock, Gladston [sic] and Steele have suggested that the continued high intake of vitamin C in early life may prevent the deposition of melanotic pigment in later years." We endeavored in the quoted article to express clearly the fact that our work had completely failed to suggest that vitamin C had any effect on the inborn error of metabolism known as alkaptonuria. We wished only to point

out that our studies did not necessarily preclude this possibility. Our statement is as follows: "It should be pointed out that the large doses of ascorbic acid were without visible effect on the ochronosis exhibited by the individual. However, these results do not preclude the possibility of a continued high intake of the vitamin in early life preventing the deposition of melanotic pigment in later years."

Indiana June Report

The Indiana State Board of Medical Registration and Examination reports the written examination for medical licensure held at Indianapolis, June 16-18, 1942. The examination covered 15 subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and twenty-eight candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
College of Medical Evangelists		(1942)	1
Loyola University School of Medicine		(1942 3)	3
Northwestern University Medical School		(1942 2)	2
Rush Medical College		(1941)	1

Nebraska November Report

The Nebraska State Board of Medical Examiners reports the written examination for medical licensure held at Lincoln, Nov 23-25, 1942. Three candidates were examined, all of whom passed. The following schools were represented:

MEDICOLEGAL ABSTRACTS

Malpractice Use of Allegedly Insufficiently Diluted Sodium Hydroxide in Allergy Test—The plaintiff was suffering from asthma and went to the Sutter Hospital, owned and operated by the appellant, the Sutter Medical Service Company, hereinafter referred to as the hospital corporation. She was received by a receptionist, who "took her history," required her to pay \$26.50 to the hospital cashier, apparently for prospective treatment, and referred her to Dr. Morgan, who was employed on a monthly salary as a resident physician in the hospital. Morgan, after examining her and a roentgenogram he had taken, sent her to a technician in the hospital building for an allergy test. The technician scraped the plaintiff's left arm in twenty-four places and dropped a solution on each abrasion, which caused a sharp, intense burning sensation concerning which the plaintiff immediately complained as the solution touched each abrasion, but the technician nevertheless continued to apply the solution until it had been applied to each abrasion. A different powder was then applied to each abrasion. The arm swelled up and became very red and painful. The technician then scraped the right arm and applied different liquids, each from a small phial, to the abrasions on that arm, but there was no sensation of burning and no untoward developments in that arm from the procedures. The left arm continued to pain and burn and the plaintiff demanded that something be done for the left arm to prevent possible infection from her coat sleeve. Dr. Morgan was then called in and directed the technician to bandage the arm, which she did, and the plaintiff left the hospital. The plaintiff could sleep but little that night because of the burning pain in her left arm. The next morning the left arm was swollen and the abrasions thereon were all "kind of greenish and [there was] pus in these openings." The plaintiff returned to the hospital and was examined by Dr. Morgan and by Dr. Jacobs, the president of the hospital corporation. On Jacob's advice the plaintiff was admitted to and treated free of cost in the hospital. After two or three days when the patient seems to have been discharged the swelling and pain in the left arm subsided, but the abrasions "were red and yellow and green." Apparently as a permanent condition, there now are small scars on the left arm where the abrasions had been which become red when the plaintiff is warm or when she is not feeling well. Alleging that her injuries were due to negligent treatment, the plaintiff eventually sued the hospital corporation and Drs. Jacobs and Morgan. From a judgment for \$3,750 rendered against the hospital corporation alone, the hospital corporation appealed to the district court of appeal, first district, division 2, California.

A group of physicians, denominated, according to the appellant hospital corporation, as the "Sutter Hospital Group of Doctors," all of whom it was alleged were employees of Jacobs, the president of the hospital corporation, had offices on the first floor of the building occupied by the hospital. While the hospital and the group of physicians had a common bank account and a common bookkeeping system the hospital corporation contended that the physicians operated entirely independently of the hospital, the physicians in the group being all employed by Jacobs and the group paying rent to the hospital corporation for office space occupied by it and being paid for their services from receipts of the group by checks in the common bank account. The hospital corporation contended, therefore, that since the negligence, if any, that occasioned the injuries to the plaintiff was that of the technician, an employee, so it alleged, of the group of physicians and not an employee of the hospital, the hospital corporation could not be liable and that liability, if any necessarily rested on Dr. Jacobs as employer of the technician. Since there had been a judgment for Jacobs and Morgan, the result of the contention of the hospital corporation, if sustained, would have been to leave the patient without remedy. The court however, doubted the truth of the contention of the hospital corporation as to the actual arrangement between the hospital and the group of physicians con-

cerned Dr Morgan said the court testified that he was employed at a monthly salary by Dr Jacobs as a resident physician at the Sutter Hospital, that at the time of his employment Jacobs said nothing to him about the group of physicians and spoke only of his taking a position as resident physician and that he knew nothing about the group of physicians until the day that he was called to the witness stand. However all this may be we do not find it necessary to inquire further into the intricacies of the relationship between the hospital corporation and the group of doctors here involved because we are satisfied that the verdict and judgment against the hospital corporation can well be rested on the doctrine of estoppel. From the facts here present the jury was entitled to find that the plaintiff relying on appearances for which the hospital corporation was responsible believed that she was contracting for medical services with the hospital corporation to be rendered by it or its agents and servants. Consequently the jury would be justified in finding that the hospital corporation was estopped to deny that the technician in giving the allergy test was its employee.

The hospital corporation apparently contended that since it could not legally practice medicine it could not be liable for the negligence of any of its servants attempting to practice medicine on its behalf. The fact said the court that the hospital corporation could not lawfully practice medicine does not avail it in an action instituted against it for the negligent act of its servants undertaking to practice medicine on behalf of the corporation. The medical service corporation either did contract or led the patient to believe that it was contracting with her for medical services. As was said in *Hannon v. Siquel Cooper Co.* 167 N. Y. 244 60 N. E. 597.

The public health law by section 164 makes it a misdemeanor for any person to practice or to hold himself out to the public as practicing dentistry without being licensed to practice as such and it would seem that the action of the defendant in attempting to carry on the business of dentistry was illegal and ultra vires. But though it was beyond the corporate powers of the defendant to engage in the business this does not relieve it from the torts of its servant committed thereon and the unanimous affirmance of the appellate division is conclusive to the effect that it either practiced dentistry or held it out as practicing dentistry.

The hospital corporation next contended that if it were held liable on the theory of estoppel to deny that the technician was its employee the verdict in favor of Dr Jacobs is fatally inconsistent with the verdict against the hospital corporation in view of the testimony of Jacobs and the technician that the technician was Dr Jacobs' employee. In support of this proposition the hospital corporation probably relied on *Bradley v. Rosenthal* 154 Cal. 420 97 P. 875 which held that where master and servant are jointly sued for the alleged negligence of the servant alone which the master did not direct and in which he did not participate a verdict in favor of the servant relieves the principal of responsibility and may be waived by the principal for that purpose. But answered the appellate court, this case does not fall into that pattern. Here the act of negligence was that of the technician and not of Jacobs and if Jacobs and the hospital corporation were liable they were both liable under the doctrine of respondeat superior. The hospital corporation's liability was in no sense dependent on any act of Jacobs and vice versa. The technician was not a party defendant and was not exonerated by the jury. The rule applying to joint feorors generally is that judgment in favor of one joint tortfeasor is not a bar to a recovery against the other. The court accordingly concluded that the judgment in favor of Jacobs cannot be taken advantage of by the hospital corporation on this appeal. The same result in any event, said the court can be as well reached in another fashion. If the hospital corporation is estopped to deny that the technician was its employee in administering the tests to the plaintiff it would seem to be equally estopped to assert against the plaintiff that Jacobs was the employer of the technician.

The hospital corporation contended next apparently, that the verdict against the hospital corporation must necessarily have been based on negligence on the part of the technician which negligence finds no support in the evidence. The technician testified that the liquid she applied to the abrasions on the

plaintiff's left arm, which was apparently the cause of the resulting injuries, was tenth normal sodium hydroxide solution which is admittedly standard for such tests. However, an expert witness produced by the plaintiff testified that such a solution is not harmful to the human body, but that sodium hydroxide is a caustic and in stronger solution will destroy the tissues. He testified further that very seldom does a reaction result from an allergy test in less than an hour and very seldom does any severe reaction from the skin scratch test of the kind made on the plaintiff's left arm occur and that as a result of the performance of the test a slight burning might result, but definitely there would not result an intense burning. Another medical witness testifying for the hospital corporation stated that if a strong solution of sodium hydroxide was placed on a scratch prur would be manifest in "ten seconds at the most, maybe before," but that there would be no pain from a tenth normal solution. This evidence, said the court, is ample, if believed by the jury, to support a finding that some corrosive liquid was applied to the plaintiff's left arm resulting in the injuries which she suffered.

The judgment in favor of the patient was accordingly affirmed.—*Hedlund v. Sutter Medical Service Co.*, 121 P. (2d) 878 (Calif. 1942).

Drunkenness Admissibility of Evidence of Blood Test—The plaintiff's husband, a policeman, died as the result of an automobile accident. In a subsequent suit by the plaintiff for a writ of mandate to require the defendant city to make an order allowing her a pension because of the death of her husband it appeared that at the time of the accident the deceased was under the influence of intoxicating liquor. From a judgment denying the pension the plaintiff appealed to the district court of appeal, second district, division 2, California.

Among other things the plaintiff contended that the trial court committed prejudicial error in receiving in evidence the opinion of certain doctors that the deceased was, at the time of his death under the influence of an intoxicating beverage. These opinions were based solely on the results of tests made of the blood of the deceased taken from him after his death. But, said the court, the opinions of qualified medical doctors as to whether or not an individual is intoxicated predicated on the percentage of alcohol in the individual's blood, although not conclusive are admissible when there is a proper showing that the blood tests have been properly conducted. (*State v. Dignud*, 50 Ariz. 276 72 P. (2d) 435; *Kuroski v. Actina Life Ins. Co.* 234 Wis. 394 291 N. W. 384; *Commonwealth v. Capolbo* 308 Mass. 376 32 N. E. (2d) 225 1 A. M. A. 119 583 [June 13] 1942). In the present case since no objection was made that a preliminary foundation had not been laid for the admission of the testimony of the qualified physicians, the trial court properly permitted them to testify that in their opinion the decedent was intoxicated at the time of his death since an analysis of his blood disclosed that it contained 0.28 per cent ethanol. Other contentions of the plaintiff were likewise overruled and the judgment in favor of the city was therefore affirmed.—*Laurence v. City of Los Angeles* 127 P. (2d) 931 (Calif. 1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Keloids—The 80 cases of keloid that Garb and Stone report were treated in private practice and at the New York Post-Graduate Hospital from 1929 to 1940. The literature is reviewed to facilitate discussion of the theory and therapy of keloids. Hormone stimulation appears to be the main or the important contributing cause of keloid formation. The fact that the keloids of 23 of 67 patients whose ages were given occurred in the second decade and 12 per cent of keloids followed acne vulgaris also point to hormone stimulation. This view is further supported by the resolution or absence of keloids after the menopause and by their rarity in the aged, possibly the result of the diminution or disappearance of the male or female sex hormone. While keloids have distinctive, usually easily recognized, features there are numerous instances in which a differential diagnosis has to be made between keloids and hypertrophic scars, sarcoids, scleroderma, fibroma and paraffinomas. Epuhis, some tumors of the throat, lung, stomach or ovaries and even esthiomene and rectal strictures are considered by many investigators as forms of keloidal growths. Primary union of a wound does not prevent the formation of keloids. Roentgen or radium treatment before or soon after excision of a keloid does not prevent its recurrence. A keloid of sufficient size should be first excised, wound healing hastened and x-rays or radium used at the first sign of recurrence. Among the authors' patients 2 are of particular interest: a girl of 18 whose hundreds of keloids did not respond to any form of therapy and a woman of 49 with extensive keloidal growths for fifteen years in whom deep ulcers and hyperkeratotic areas developed.

Treatment of Burns—Since October 1939 Hamilton has compared the efficiency of foille (a thick, soapy water-in-oil mildly antiseptic emulsion), cod liver oil, cod liver oil ointment, tannic acid with and without silver nitrate and 3 per cent sulfadiazine in 8 per cent triethanolamine in a large charity hospital

with inadequate nursing care and lacking in ideal facilities for treating burns. Such conditions are likely to prevail in military hospitals in wartime. The series discussed consists of one hundred and ninety-nine burns in 192 hospitalized patients. Seven bilaterally similar burns were dressed with a different agent on either side. Thirty-eight of the 192 patients died. There is some slight excuse for this appalling figure: nursing care was inadequate; there were no facilities for isolation and/or special care, the amount of plasma available was greatly inadequate for 10 and moderately so for 6 patients; the burns of 6 patients involved 50 per cent of the total surface of the body and a number of patients were in the extremes of age or were suffering from serious organic disease. The postmortem examination of 12 revealed generalized congestion of viscera, especially of the lungs, intestine, adrenals and spleen. The liver was the organ most frequently and seriously deranged. From the mortality and survival rates foille, tannic acid and sulfadiazine were about equally effective in the saving of life. The burns treated with cod liver oil were too few and too small for the efficacy of this compound to be evaluated. Foille has been criticized on the grounds of the possible toxicity of its phenol content, but the author's impression and the mortality and survival statistics do not substantiate this criticism. Regarding the sloughing stage of third degree burns it appears that burns treated with foille rid themselves of slough sooner than those dressed with other agents. Also with foille there was a significant reduction of healing time of the third degree burns over that with tanning or by the sulfadiazine spray. The second degree burns healed slightly earlier with leatherizing treatment than did those treated with foille. Foille appeared superior to the control agent in the 7 patients with bilaterally comparable burns who were treated simultaneously with two different agents. The sulfadiazine spray seemed to be somewhat more bactericidal than the other agents at least for *Streptococcus hemolyticus*. In respect to relief of pain no pronounced difference between the agents was revealed although tannic acid was somewhat superior and cod liver oil somewhat inferior. The end results are difficult to evaluate, but it appeared that the healing of the deeper burns, especially of the face, hands and flexures was somewhat less painful and that there was less tendency toward contracture when they were treated with foille than when they were treated with other agents.

Sulfaguandine—Veta and Stevenson used sulfaguandine as an intestinal antiseptic in treating 20 women and 7 men between 31 and 72 years of age. They present a method of determining the presence of the drug in the feces. The administration of sulfaguandine definitely reduced the coliform organisms in the intestine of 18 of the 27 patients. When ulcerative intestinal lesions were present a significant reduction in the coliform organisms was not obtained by sulfaguandine. This limits the beneficial results that could be expected. Its use altered the blood picture in only 1 of the 27 patients. Nevertheless it is advisable to check the blood counts of those receiving the compound in order to detect the occasional patient whose hemopoietic system is sensitive to it. The other 26 patients showed no other significant toxic reactions. Sulfaguandine by depressing the coliform bacteria interferes with the synthesis or absorption of vitamin K by some patients. Crystalluria with subsequent formation of concretions might be considered a hazard but this complication can be overcome by an adequate fluid intake. Sulfaguandine is not the ideal chemotherapeutic agent for intestinal antiseptics. A sulfonamide which would destroy all the intestinal bacteria and still have the slow absorption and low toxicity of sulfaguandine is the desired drug. The studies on absorption and excretion of the compound reveal that there is a decided variation in the amount of compound absorbed by each individual patient. However, unlike other sulfonamide compounds, sulfaguandine is relatively poorly absorbed from the gastrointestinal tract and thus it remains in the intestine in a sufficiently high concentration and acts as a local chemotherapeutic agent. The portion (mean average 14.2 per cent) of the compound that is absorbed is rapidly eliminated in the urine and high blood concentrations are not usually found.

Carcinoma of Breast—Haagensen and Stout discuss the data from a punch card method utilizing a summary sheet listing some 700 different items found in the study of the mammary cancer of 1,040 women with proved or presumed carcinoma of the breast coming to the Presbyterian Hospital in 1915 to 1934. Of these, 986 were accepted for study and detailed unit records. The fact that in 66 per cent an unsuspected carcinoma was discovered during a routine physical examination is striking proof of the value of a careful and complete physical examination of every patient. Only 16 per cent of the patients sought medical aid because of pain in the breast. The cancers of 876 of 986 women were relatively operable and of 640 absolutely operable. In 236 a radical operation was not done because of constitutional inoperability, the extent of the carcinoma, death refusal or primary erroneous diagnosis in 10. Of the 640 primary cases treated by radical mastectomy, 599 were followed until death or for a minimum of five years. The term 'five year clinical cure' is used to designate the group of patients in whom no further evidence of cancer developed during the five postoperative years. Twenty patients died at operation, 41 were lost track of before the five years were up, 13 died of unknown causes and 12 of intercurrent disease during the five years. 290 died because of their disease, while 33 with recurrence and 231 without recurrence are alive five years after operation. A local recurrence developed in 146 and metastasis in 316 within five years of the operation. The earlier the patients came for treatment the better was their chance of clinical cure. The clinical cure rate of those in whom the disease was limited to the breast was approximately three times as high as of those in whom it extended to the axillary lymph nodes. The frequency of local recurrence appears to be similarly related to axillary involvement. Only from the knowledge obtained from an accumulation of actual measurement of the axillary nodes can one hope to become more expert in his judgment of axillary involvement. Preoperative radiation is not given to patients with operable carcinoma of the breast. Postoperative prophylactic radiation has not appeared to have had any demonstrable value. Palliative irradiation for recurrent disease has been of the greatest value in controlling pain due to bone metastasis and in clearing up small local recurrences in the operative field. When persistent pain develops in the back, pelvis or legs of a patient who has had a radical mastectomy for carcinoma irradiation is begun at once, even though roentgenograms fail to reveal any definite lesion of the bone. During the years covered by the present report there was an

increasing tendency of the staff surgeons to lengthen the operative time and to increase the extent of the dissection. The evidence suggests that these more radical operations gave better results.

Massive Rupture of Liver—Pilcher believes that his patient is the fourth to recover from massive rupture of the liver complicated by a triple rupture of the right kidney. The massive rupture was satisfactorily repaired with only three interrupted No. 2 chromic sutures. There was little postoperative oozing. This shows that when lacerated liver tissue is accurately approximated the ruptured bile sinuses and blood vessels heal rapidly. The danger of infection when bile sinuses are opened is well known and it would undoubtedly be safer to assume that infection will be present and give sulfonamides (sulfanilamide locally and sulfadiazine by mouth or parenterally) from the beginning. The use of large gauze packs is at best a crude and primitive form of treatment and, although they may at times be a necessary life saving procedure, they must frequently be considered as a confession of lack of surgical judgment. As this case illustrates some phases of surgery on the liver should not be considered hopeless.

Hepatic Necrosis—With definite experimental evidence of the responsible factors of acute hepatic lesions in hyperthyroidism Sealy studied the 8 necropsy cases collected by the department of pathology of the Duke Hospital to determine whether hepatic necrosis existed in acute hyperthyroid reactions and, if it did, what its relation was to other factors. Seven of the patients died from an acute hyperthyroid reaction and 1 as a result of a pulmonary embolus on the fourteenth postoperative day. Evidence of acute pathologic changes of significant proportions was seen in the liver of 3 of the 8 patients. The structural alterations of 2 consisted in decided focal necrosis and fatty degeneration. The acute changes in 2 were complicated by moderate passive congestion and in 1 in addition to these changes well defined periportal scarring and polymorphonuclear and lymphocytic cellular infiltration were seen. The areas of necrosis were focal and could be separated from the slight changes resulting from passive congestion. One of the 3 patients was apparently well prepared for operation and had no clinical evidence of cardiac failure but passive congestion was present, even though death occurred only nine and a half hours after operation. Extensive central fatty change, associated probably with passive congestion, was present in his liver. The acute changes in the livers of the remaining 5 patients were insignificant. As to chronic lesions, such as periportal scarring they were significant in 4 of the 8 and in 4 the damage was slight or absent. In 1 of the latter hyperthyroidism had been present for two years and in 3 only for six months. This seems to be significant, a similar relationship of the duration of the toxicity with the degree of chronic change has been observed by Beaver and Pemberton.

Normal Cardiac Response—The effect on the heart from submersion incident to swimming in 68 college women was studied by Tuttle and Templin. In 7 there was no decrease in heart rate. On the average, the decrease in the 61 was 13 beats per minute, which is practically the same as that reported for men. The extent of the decrease varied directly with the resting pulse rate. There were two possible explanations for the abnormal response of the 7 girls who failed to respond normally to submersion in water: lack of psychologic (emotional) adjustment, that is, they were afraid, and lack of physiologic adjustment. When emotional factors are controlled, failure to experience a significant drop in pulse rate during submersion in water below body temperature indicates sensitivity to the water. "Submersion syndrome" is suggested for the conditions that prevent a normal adjustment to submersion in water.

Epidemic and Postoperative Hiccup—The study of the epidemiologic characteristics, etiology and serum treatment of persistent epidemic hiccup has been extended by Rosenow to that of persistent postoperative hiccup. The cases studied culturally and those in which serum was used in treatment were seen chiefly at the Mayo Clinic. Persistent hiccup occurred in unusual numbers throughout the spring and autumn of the years of this study (1927 to 1941). It was related to mild outbreaks of respiratory infection. It usually occurred in men from 17 to 82 years of age. The data from laboratory studies (isolation of the spasm producing type of streptococcus from the nasopharynx, milk supplies and outdoor air during epidemic prevalence of hiccup and certain respiratory infections and from the air of rooms occupied by persons having persistent hiccup) indicate that the incidence of epidemic and postoperative hiccup is increased when streptococci normally present in throats of persons and in nature generally acquire spasm producing properties or virulence. Persistent epidemic and postoperative hiccup are considered to be forms of mild myoclonic encephalitis. The inciting agent is a streptococcus (*Streptococcus singultus*) closely related to the streptococcus of epidemic encephalitis. Antistreptococcus serum for epidemic encephalitis is curative in persistent hiccup.

Pneumococcal Pneumonia Treated with Sulfonamides—Schwartz and his collaborators compare the therapeutic effectiveness and toxicity of the sulfonamides in the treatment of recurrent pneumococcal pneumonia in 24 patients. The time interval between readmissions (1 patient was readmitted twice) ranged from four to ninety-two weeks, with an average of thirty-seven weeks. Typable pneumococci were found in the sputum or blood stream of 35. The same pneumococcus type was the causative agent of subsequent attacks in only 4 patients. There were two deaths among the twenty-five subsequent admissions, both of patients with type III pneumonia. The first attack of 17 patients was treated with sulfapyridine and the result was good in 13 and fair in 4, and good in 4 and fair in 3 of the 7 treated with sulfathiazole. For the subsequent

attacks the figures for sulfapyridine are 8 and 1 (and 1 patient died), for sulfathiazole they are 8 and 1, and for sulfadiazine they are 4 and 1. The third attack of the 1 patient who died was treated with sulfapyridine. The drugs appear just as effective for subsequent attacks as for the initial one. There was no evidence suggesting that the repeated use of a sulfonamide increased the incidence or severity of drug toxicity. Vomiting and microscopic hematuria were the only toxic reactions worth mentioning.

Mediastinal Glands in Undulant Fever—In an attempt to explain the pathologic changes that cause the dry, irritable and nonproductive cough in undulant fever, Martin presents histories of 3 of 6 patients with this type of cough. In all 6 the roentgenogram revealed moderate and decided enlargement of the mediastinal nodes. In 3 of them the agglutination was never positive, but in the other 3 it was conclusive.

Hemolytic Streptococcus Bacteremia—Rantz and Kirby point out that other than group A hemolytic streptococci are frequently the cause of serious infection in man. In only 6 of the 13 consecutive cases of hemolytic streptococcus bacteremia observed by them in Stanford University Hospitals were group A organisms the etiologic agents. In 4 the hemolytic streptococci were of group B, in 1 of group C, in 1 of group D and for 1 the data are not given. On sulfonamide therapy 2 patients recovered and 2 died. The favorable effect of sulfadiazine in 1 of them with pneumonia and suppurative arthritis complicating chronic lymphatic leukemia was most remarkable. Two patients

with group B infection were treated with sulfapyridine, in 1 postoperative meningitis appeared to be subsiding at the time therapy was instituted and in 1 with puerperal sepsis sulfanilamide was without effect, but a change to sulfapyridine was followed by prompt recovery. One patient with group C infection recovered after sulfadiazine therapy in spite of aplastic anemia with agranulocytosis. The drugs of the sulfonamide group have been demonstrated in a previous study to be without effect in group D infection. Evidence suggests that sulfanilamide may not be of value in serious group B infection. The determination of the serologic group of the streptococcus is chemotherapeutically of definite importance.

Therapeutic Use of Radioactive Substances—Low-Ber and his associates review the physical and biologic background of internal radiation therapy. The distribution and metabolism of radioactive phosphorus in animal and in human tissue indicate its therapeutic value for certain diseases particularly chronic leukemia and polycythemia vera. The therapeutic effect of a millicurie of radiophosphorus is not to be expected to be comparable to a millicurie of radon. The internal use of radiating agents such as radiophosphorus, requires a new orientation of the concept of the distribution of radiation in the body. A means of calculating the "radiation level" in the body of a patient on any day after either one or multiple doses of radio-phosphorus is described, and although it does not account for the selective distribution of the radiating agent and cannot be exactly accurate for any single patient, owing to different rates of elimination, it does provide a more satisfactory means of approximating the active amount of radiation at any given time than do dose and the time of administration. The determination of the "radiation level" is of greater value with small, frequently repeated doses than when single doses are used at long intervals. Small fractionated doses seem justified for the following reasons: 1. By keeping a fairly constant, though low, level of radiation in the body for a considerable time, more cells are likely to be affected during their most sensitive period. 2. As actively growing cells take up a greater proportion of phosphorus than "resting" cells, a continuous supply of radioactive phosphorus is more likely to result in the radioactive atoms getting into dividing cells. It is too soon to compare the results of infrequent single with fractionated radiophosphorus treatment and also with other methods, but some remark-

able and some unsatisfactory responses have been obtained with varying dose methods in chronic myelogenous leukemia, chronic lymphatic leukemia and lymphosarcoma. Until end results justify frequent small doses, this technic cannot be advocated as the method of choice. The treatment of polycythemia vera differs from that of the three aforementioned diseases in that the aim is to influence the erythropoietic tissue adversely instead of trying to "protect" it. A higher level of radiation is required. Many complete remissions have been produced. Patients with Hodgkin's disease have not had as satisfactory responses as those with lymphosarcoma. Multiple myeloma and widespread metastasis from carcinoma have proved resistant, even though a few satisfactory palliative results have been obtained. The use of other radioactive elements (strontium, iodine, element 85 and phosphorus in chromium phosphate) is proving their value in some conditions. The use of radioactive elements in various compounds which might localize in certain tissues is an unexplored field with great potentialities.

Treatment of Lymphosarcoma with Radioactive Phosphorus—The results of radioactive phosphorus therapy in 22 unselected patients with lymphosarcoma have been carefully studied and analyzed by Kenney and Craver. Ten, or 46 per cent, of the 22 patients are living, 4 of them have had complete remissions and have had no recurrence for three to twelve months, 2 have had recurrences which were controlled by additional therapy, in 3 the disease has regressed 75 per cent and in 1 about 50 per cent. Six of the 10 living patients have had previous roentgen therapy, which had controlled the disease completely in 3 and partially in 3. Of the 12 patients who died 10 were never benefited by isotope therapy. Eleven received roentgen therapy without effect subsequent to the radioactive phosphorus. Five of these had had roentgen therapy prior to treatment with radioactive phosphorus with partial control in 2 and no control in 3. The disease of 5 was clinically classified as leukosarcoma, the acute phase of lymphosarcoma. The period of remission, which is still unbroken in the successfully treated patients, has been longer in 2 patients than after previously administered courses of roentgen therapy. In 5 of these patients the remissions have been longer than the average of six to nine and a half months given by Medinger and Craver for roentgen treated patients. A tentative method, based on the differential absorption ratio, for selecting patients suitable for radioactive phosphorus therapy and for determining whether to use it as a primary or secondary method is outlined. From the results, it appears that the therapy should be used primarily or secondarily for virtually all cases of lymphosarcoma.

Treatment of Cancer with Fast Neutrons—Between December 1939 and Sept. 15, 1941 Stone and Larkin treated the cancers of 120 patients pronounced incurable by surgical or roentgen measures with the 60 inch cyclotron producing neutrons with 16 million electric volts of energy. The anatomic distribution of the lesions was the tongue 18, prostate 18, skin and lip 13, floor of the mouth and alveolar ridge 13, breast 11, larynx and pyriform sinus 9, stomach and intestine 9, buccal mucosa 5, brain 4, nasopharynx 3, parotid 3, esophagus 2 and miscellaneous 12. Only 1 patient had a small localized tumor, 31 had lesions with definite local extension without metastasis, 34 had advanced primary lesions and metastasis and 49 had recurrences, usually after previous roentgen or radium treatments. Of the 120 patients 61 had died by Oct. 15, 1941. The encouraging facts are that, of those who were alive on Oct. 15, 1941, 9 had survived almost one year, 3 for twelve to fifteen months and 10 for more than fifteen months. Sixteen of those who survived had cancer of the prostate—a disease that does not always cause rapid death even if untreated. Of the 61 patients who died 26 did so either because their tumors were uncontrolled or because irradiation brought about conditions incompatible with life, and 31 had a gross tumor at the time of death in the region treated. Twenty-nine of the 41 patients with cancer of the mouth or throat had persistent ulceration at the time of death. At the end of treatment about 17 per cent of them showed complete regression and about 48 per cent showed partial regression of the tumor. After trials of various technics, it was concluded that 70 to 75 neutrons, as measured in the authors' laboratory, given to a single field with no cross fire on alternate days, was best. As judged by the minimal

threshold skin reaction, 1 neutron was found to be equal to 6 roentgens. As judged by the cutaneous reaction occurring about the neck and face, about 700 neutrons to a single field and 500 neutrons to two opposite fields administered in about twenty-six days produce an epidermitis which heals satisfactorily. The data demonstrate that cancer can be favorably influenced by neutron therapy and that normal tissue recovers from specific exposures. Therefore it should now be permissible to treat small cancerous lesions, which are more likely to be "cured" than the extensive ones. Further studies must establish the methods best suited to neutron therapy.

Treatment of Acne Vulgaris—One hundred and thirty of the 169 patients with acne vulgaris that Smith treated with 75 roentgens once a week obtained a final satisfactory result. Also the condition of 23 patients was definitely improved and that of 16 was slightly or not improved. As many factors influence acne vulgaris, attention to them is important in the successful treatment of the disease. Of the several forms of physical therapy used for hastening cure, irradiation is of most value. It is important that sufficient treatment (twelve or more exposures) be given to prevent relapse, overtreatment must be avoided. Roentgen therapy is the least favorable for early cases. Of 100 patients more than 16 years of age, receiving twelve or more treatments of 75 roentgens each, 89 per cent obtained satisfactory results. This percentage could probably be increased if proper cooperation of all patients could be obtained and appropriate follow-up treatment given. Ultraviolet radiation is sometimes of temporary benefit. It is most useful as a desquamating agent between or after courses of roentgen therapy. Mild freezing with carbon dioxide slush is worth trying if roentgen therapy is not advisable, and as a later desquamating agent. Ultraviolet therapy should not be used concurrently with roentgen therapy.

Circumcorneal Injection and Ariboflavinosis—Among 204 persons between 12 and 69 years of age seen in the outpatient department from October 1941 to March 1942, when the nutritional deficiency might be expected to be at its peak, Scarborough observed that 70 had circumcorneal injection. This sign occurred with relatively greater frequency among the older patients. 43 of 63 persons older than 50 were so affected. The observation of Sydenstricker and his co-workers that circumcorneal injection occurs in ariboflavinosis has been confirmed, but a form of the condition exists even in subjects presenting evidence of frank vitamin deficiency disease which cannot be attributed to a deficiency of riboflavin, as it is not cured by the administration of the vitamin. The latter observation no doubt accounts for the relatively high incidence of circumcorneal injection observed. Although circumcorneal injection may be an early stigma of ariboflavinosis it cannot be so considered unless it is supported also by the presence of cheilosis, glossitis, dermatitis and ocular symptoms or by slit lamp examination of the cornea. Certain of the subjects manifest a requirement for riboflavin which, for reasons unknown, is unusually large. Clinically, the circumcorneal injection differs in no material way from that described by Sydenstricker in frank ariboflavinosis.

Treatment of Bacillary Dysentery—At a recent medical conference in the Middle East it was agreed that it is better to do nothing at all for patients with bacillary dysentery than to give them salines which dehydrate an already dehydrated patient. Pauley's results among a large group of patients treated last year on "do nothing plus fluids" lines were at least as good as those obtained at the same time with patients given saline solution. The tendency of most patients to get better anyway is disturbing because if the disease is mild (which form has predominated this year) it leads to complacency. The results of five types of treatment are compared. There were no failures among 43 patients treated with sulfapyridine at one hospital and among 30 at another hospital. Of 25 given sulfaguanidine 2 had to be given sulfapyridine and 3 others gave a poor response. The treatment of 60 patients with saline solu-

tion was prolonged (ot 1 for sixty-five and of 11 for more than twenty days), but the final result was recovery, in a few severe and chronic infections sulfaguanidine was used. Of 15 treated with koalin 2 required sulfapyridine. The average time in bed for the five groups of patients was approximately four and a fourth, five, five and a third, twelve and a half and six days. In the treatment of an isolated and severe epidemic of Shiga dysentery in one camp both sulfapyridine and sulfaguanidine were efficacious, but the period of therapy was generally longer than it was for the bacillary dysentery. As there were no cases of dysentery in this or an adjacent camp for three months, the cause of the outbreak was possibly a carrier in a draft of 70 men who had arrived from India about seven days before the dysentery began. The number of stools was reduced and the blood and mucus in them disappeared more rapidly among patients treated with sulfapyridine than among those on sulfaguanidine. Also patients on sulfapyridine became afebrile within twenty-four hours as compared to four or five days for sulfaguanidine. Sulfonamide treatment brings about a rapid recovery, solid food can be taken early, convalescence is short and discomfort is quickly curtailed. The disadvantage is crystallization in the renal tubules with anuria. In the Middle East supply and cost must also be considered, but from the military and civil aspect this is outweighed by the shortened period of noneffectiveness. Treatment should be begun before the disease has spread or become chronic.

Scabies and Intelligence—Mellanby and his co-workers assessed the intelligence of several hundred patients with scabies. The results indicated that the men with scabies were mentally an approximately normal sample from the army. There was nothing to suggest that the group contained an abnormally high proportion of men of low grade intelligence. There was no significant difference in intelligence between men who reported themselves sick, those who were detected at routine inspections, those with few or with many parasites or those with or without secondary infection.

Influenza Epidemic in Military Camps in Victoria—Typical virus influenza occurred in Victoria and in the military camps near Melbourne in May 1942. Burnet and his co-workers tried to establish whether this epidemic was true virus influenza and, if so, to determine the type of virus. Virus was readily isolated by the amniotic method and produced decided temperature responses in ferrets. Patients with typical symptoms showed a sharp rise in antibody in the fortnight following the illness. The only anomalous feature was the season at which the epidemic appeared. Unusually cold wet weather in addition to camp conditions may have been wholly or partly responsible for this change. Serologic studies only confirmed the relatively homogeneous character of the epidemic in only 1 subject with typical symptoms was the rise insignificant. Comparison with an unselected camp population confirms the general finding that susceptibility to influenza is significantly correlated with an initially low antibody level, however, a relatively high antibody level is no guaranty of immunity. It is the authors' impression that nonspecific inhibition by serum protein plays an important part in determining the initial titer of a given subject and that specific antibody inhibition is superimposed on this nonspecific effect. This aspect must be clarified before the significance of detailed serologic studies on specimens of serum by Hirst's method can be discussed or determined.

*Clinical Picture of Interstitial Plasma Cell Pneumonia in Infant. E. Hug—p. 2.
Relation Between Enuresis and Epileptic Crises in Children. M. Schachter—p. 19.
Nutritional Metabolic and Digestive Disturbances in Children with Malaria. A. Eckstein—p. 25.

Interstitial Plasma Cell Pneumonia in Infants—Hug believes that plasma cell pneumonia is a distinct entity. He reviews histories of 8 instances observed in his clinic, all of them in premature infants. Four of these died and were subjected to a necropsy. The author suggests that this type of pneumonia is probably not caused by infection but is due to improper method of nursing. The condition develops as a result of repeated aspirations of small amounts of food because of careless feeding technique of premature infants who are difficult to feed. This opinion is supported by the postmortem status described by Roulet, who found that the microscopic picture of this type of pneumonia greatly resembles that of aspiration pneumonia. He believes that the increase in the interstitial tissue and its dense infiltration with plasma cells are manifestations of a reaction on part of the lung to a substance consisting, as milk does, chiefly of protein and fat. The close relationship of plasma cells to protein decomposition is well known.

Traumatic Luxation of Hip in Children. L. Velasco Blanco and E. M. Echegaray—p. 64.
Sulfonamide Therapy in Ophthalmologic Disorders in Childhood. B. V. Re—p. 71.
*Case of Fatal Intoxication by Sulfanilamide and Sodium Sulfate. A. F. Parodi and T. R. Lora—p. 75.

Fatal Intoxication by Sulfanilamide and Sodium Sulfate—Parodi and Lora's patient was a woman aged 31 who complained of malaise, coryza, sore throat and cough. A physician diagnosed her disorder as influenza and prescribed sulfanilamide, of which she took 2 Gm. on the day of the consultation. In the evening of the same day the woman took a purgative dose of sodium sulfate. On the following morning she exhibited severe dyspnea, cyanosis and stupor. Oliguria had existed since the night before. She was hospitalized at 11:30 a. m. in a comatose condition and died at 4:30 p. m. The circulatory, respiratory and hematologic symptoms were the result of a severe anoxemia caused by the combination of sulfanilamide with sodium sulfate, which led to the formation of sulmethemoglobin. Paton and Laton reported in 1937 that the simultaneous administration of azosulfamide and the sulfates of sodium or magnesium and purgatives produce grave intoxications. According to Parodi and Lora the therapeutic procedures recommended include intravenous injection of methylene blue, oxygen therapy and blood transfusion. In their case death ensued before a transfusion could be carried out. Chilean authors did not see any advantage from the use of nicotinic acid as recommended by Ginty. The authors stress that sulfanilamide is incompatible with a number of other drugs, such as gold, arsenic bisulfide, sulfur compounds, particularly purgatives, antipyrine and aminopyrine. Alcohol should be abstained from during the use of sulfanilamide in order to avoid cerebral symptoms. Hepatic and renal functions should be determined before and during this medication. The blood is to be watched for the appearance of anemia or agranulocytosis, and the blood and urine concentration of the drug should be determined.

*False Jaundice. Cutaneous Anthochromia Caused by Hypercarotenemia. J. Yepes Cadavid—p. 103.
Chronic Appendicitis and Benign Traumatic Diverticulitis. C. García Mayora—p. 105.

False Jaundice—According to Yepes Cadavid, cutaneous anthochromia results from abuse of a vegetarian diet sometimes employed to obtain a laxative action. Excessive intake of foods such as carrots, green vegetables, papaya and sapodilla causes an overflow of the hepatic carotene storage and thus

results in a pseudoicteric appearance of the skin. This pigmentation frequently remains localized on the palms of the hands and feet but may involve all of the skin. The author cites 2 women, aged 48 and 18, who had eaten excessive quantities of papaya to relieve constipation. Both patients developed a generalized pigmentation, but their conjunctivas were clear and the urine was free from biliary pigments. The coloration was of an orange or saffron shade and was especially evident over the neck. Mild xanthochromia was present in the sublingual mucosa. The causal agent of this disorder is the yellow coloring matter carotene, of which certain plants contain abundant amounts. The liver transforms this provitamin into vitamin A by means of a ferment. Large amounts of carotene in the food exceed the capacity of the liver to utilize it, and hypercarotenemia results. Hypercarotenemia may develop in the absence of alimentary excess of carotene as a result of hepatic insufficiency which impairs the metabolism of this pigment. Carotene exists in the blood from birth in quantities that increase somewhat with age. Under normal conditions the carotene content varies between 0.3 and 0.7 mg per liter. In patients with xanthochromia it reaches up to 3 mg per liter. *Cutaneous xanthochromia* of hypercarotenemia is a benign transitory disorder which improves with the suppression or limitation of carotenophorus foods and the stimulation of liver by injectable liver extracts.

*Aneurysm of Peripheral Arteries in Course of Subacute Bacterial Endocarditis. M. R. Castex, E. S. Mazzei and A. Lavarello—p. 1
Physiopathology of Yellow Body. F. Bergamini—p. 8

Aneurysm of Peripheral Arteries—Castex and his collaborators report 2 cases of aneurysm of peripheral arteries in the course of a subacute bacterial endocarditis. The incidence of aneurysm in subacute bacterial endocarditis is greater in patients of the ages between 20 and 40 than in the young and the old. It involves peripheral arteries as a rule. It may be multiple and may appear in one or all of the extremities. *Streptococcus viridans* alone or with other bacteria is the organism more frequently identified in the walls of the aneurysm. The aneurysm appears suddenly and is usually very painful. True subacute peripheral aneurysm of endocarditis is circumscribed and limited. Frequently it ruptures spontaneously and produces either a diffuse or a false aneurysm. A large hematoma about the ruptured aneurysm is the most obvious anatomic sign of a false aneurysm. The microscopic changes are variable. They may show local inflammation, endothelial obliteration of the vasa vasorum and ischemic necrosis of the arterial wall or blood infiltration of the arterial walls, which is an equivalent of a local suppuration. Peripheral arterial aneurysm is of diagnostic value in recognition of a subacute bacterial endocarditis. The fatal course of endocarditis is not the result of the aneurysm. The treatment of the aneurysm consists of a compressing bandage to control the pain. The surgical treatment consists of ligation of the artery or of extirpation of the aneurysmal segment. It is indicated in cases of intractable pain and threatened rupture.

Glomus Tumors—Ley and Roca de Viñals describe 2 cases of glomus tumor. The first patient, a man aged 50, had a small nodule on the outer aspect of the forearm. The nodule grew slowly. In the last months it had caused extremely pain-

ful crises. The pain radiated into the arm and the shoulder and at times involved the whole left side of the body, producing a sort of hemiparesis which persisted for several seconds. The nodule, the size of a grain of rice, was adherent to the skin. It was diagnosed as glomus tumor and was removed. The pain ceased after extirpation and did not recur. The second patient was a girl aged 18. The condition was atypical in symptoms and localization. This patient complained of paroxysmal pains in the right hand. For several months previous to her seeking medical aid the pain had become more severe with greatest intensity in the ring finger. The pain was accompanied by tumefaction, cyanosis and loss of power. Neurologic examination revealed the syndrome of Claude Bernard-Horner. On the basis of a tentative diagnosis of polyarthritis of the chronic inflammatory type, combined administration of salicylate and sulfanilamides was tried, but without effect. Fever therapy likewise failed. Roentgenograms of the hand revealed a cystic formation in the first phalanx of the right ring finger. On removal the growth appeared as a round bluish red tumor measuring about 9 mm. It was lodged almost completely in the bone. It was designated as a *glomus tumor on the basis of microscopic examination*. The pain ceased immediately after the operation and did not recur. Intraosseous location of a glomus tumor is exceptional. Association with the Bernard-Horner syndrome is interesting. It was reported by Barre in a case of subungual glomus tumor. It is suggested that the syndrome is due to abnormal stimulus resulting from hyperplasia of the peripheral neuromyoarterial organ provoking by reflex action inhibition of the cervical sympathetic, this in turn confirming the importance of the role of the "cutaneous glomus" in the regulation of the peripheral circulation.

Adamantinoma of Nose—According to de Juan and Oliva adamantinomas which originate from the epithelial remains of the enamel organ usually develop in the maxilla, particularly the lower one. Literature contains reports of other localizations of this type of tumor, such as tibia, sella turcica, hypophysis, sphenoid, ovary, pharynx and parotid. There appears to be no record of an adamantinoma located on the tip of the nose. The authors' patient was a woman aged 81, who developed an adamantinoma of the tip of the nose, which rapidly grew from the size of a grain to that of a hazelnut. The growth was excised at its pedicle, and the resulting wound cicatrized completely in the course of eight days.

Syndrome of Ehlers-Danlos—Roca and his associates report 2 cases of Ehlers-Danlos syndrome in two brothers aged 26 and 23 respectively. The disorder is a rare dystrophy, frequently congenital and hereditary and almost always familial which involves mesenchymal tissues and is characterized by abnormal elasticity and vulnerability of the skin, articular looseness and formation of cicatrized molluscoid pseudotumors. It was described in 1890 by Ehlers, while Danlos added to its knowledge in 1908. It may appear in either sex but seems to have a predilection for the male. The prominent symptoms are hyperelasticity of the skin, articular looseness, molluscoid tumors resulting from the abnormal vulnerability of the skin and a tendency to hemorrhages. In the 2 cases photographs demonstrate the great elasticity of the skin particularly in the region of the elbow. Biopsy specimens of the skin in this region disclosed an abundance of elastic fibers and of collagenous tissue and lymphoplasmocytic infiltration particularly at the papillary

and deep boundaries of the dermis and around the vessels. The syndrome is to be differentiated from cutis laxa, chronic atrophic dermatitis, elastic pseudoxanthoma, juvenile xanthoma, Recklinghausen's disease, chronic atrophic dermatitis of Pick-Hersheimer and geromorphism of Souanet and Charcot. The syndrome persists throughout life, but the hyperelasticity of the skin and joints tends to decrease in the course of years.

Cure of Wounds with Glass Dressings—Giordano experimented with glass dressings intended to put the wound at rest and to permit of a continuous supervision of the healing process. The glass dressings are concave plates applied over the wound and fastened with adhesive strips. The dressings have small openings on the sides for ventilation. They represent a saving in material and diminution of pain for the patient. The dressings are advantageous in postoperative wounds and particularly in wounds that heal by secondary intention.

Role of Internist in Military Medicine. E. I. Smirnov—p. 3.
Attacks of Accelerated Cardiac Activity and Their Clinical Significance. A. M. Sigal—p. 11.

*New Methods in Surgical Therapy of Cardiac Ischemia. B. P. Kirillov—p. 40.

*Dynamic Changes of Electrocardiogram After Heart Wounds. D. F. Presnyakov—p. 51.

*Cure of Agranulocytosis by Transfusion of Blood from Leukemic Patient. I. M. Rybakov—p. 70.

Surgical Therapy of Cardiac Ischemia—Kirillov maintains that an artificial collateral blood supply may be provided for the heart and that it develops especially well in those cases in which there is a physiologic need, that is, in cases of impaired cardiac circulation. After creation of a collateral blood supply the ligation of the coronary arteries does not interfere with cardiac function of experimental animals. While other tissues, such as the large pectoral muscle and the lung, have been used as sources of collateral circulation, Kirillov considers the omentum most satisfactory for this purpose. Anastomoses between the heart and omentum develop within two to three weeks and are not obliterated later (as demonstrated in experiments prolonged for more than a year). The newly formed anastomoses appear in the form of fine capillaries uniting the arterial network of the omentum with the vascular system of the heart. It is not necessary to suture the omentum to the heart. After preliminary scarification of the epicardium the omental tissue is brought into close proximity to it. If the epicardium is left intact the adhesions which develop may not extend along the entire surface of contact between the omentum and the heart. In addition to serving as a source of collateral blood supply the omental tissue may serve as an anastomotic bridge across which the blood can flow from the normal part of the heart to the part with impaired circulation. The simplicity of the author's technique guarantees a low postoperative mortality. Instead of the transdiaphragmatic route used by O. Shaughnessy, Kirillov pulls the omentum through a subcutaneous tunnel above the ribs. In man this operation can be performed without opening the pleura. The time required is no more than twenty-five to thirty minutes. While at present artificial vascularization of the heart is largely confined to experimental animals, Kirillov believes that it will soon become an accepted procedure in surgical practice.

Electrocardiogram in Heart Wounds—Presnyakov presents a table summarizing the electrocardiographic findings in various types of heart wound as recorded in the literature. He reports a case of knife wound of the right ventricle in which an electrocardiogram was obtained soon after the injury and was repeated daily for a long period. The most pronounced characteristic was a considerable displacement of the ST segment. With a few exceptions the electrocardiographic changes resembled those observed in myocardial infarction of the anterior wall. The author attributes these differences from the typical electrocardiogram of infarction to the fact that in this case the large branches of the coronary vessels were not involved in the injury. Electrocardiography in cases of heart wounds is a

valuable aid in diagnosis and localization. It may also facilitate topical diagnosis of myocardial lesions in various diseases, especially in infarction.

Transfusion of Leukemic Blood in Agranulocytosis—Rybakov reports the case of a 36 year old man who was admitted to the hospital with symptoms of extreme weakness, sore throat and fever. Because of a history of malaria and the presence of malarial parasites in the blood, tropical malaria was at first considered as a diagnostic possibility. But the granulocytopenia (93 per cent) and necrotic foci in the oral cavity led to the recognition of a disease of the agranulocytic type possibly exacerbated by malaria. Transfusion of leukemic blood was decided on and antimalarial therapy was postponed. A patient with chronic myeloid leukemia in a state of remission after roentgenotherapy was selected as donor. His leukocyte count was about 30,000, with 25 per cent embryonic forms. He was of the same blood group as the patient with agranulocytosis. Within four days after the transfusion, the blood picture had gradually returned to normal with an increased number of leukocytes and 58 per cent of neutrophils. The temperature remained normal from the third day on. Within five or six days the necrotic foci in the oral cavity were covered with healthy granulation tissue, the mucous membranes resumed their normal color and the bad odor and profuse salivation disappeared. After a course of antimalarial therapy the patient was discharged fully recovered.

Certain Peculiarities of Craniocerebral Gunshot Wounds in Present War as Observed in Hospital Practice. V. A. Gusynin—p. 5.
Late Primary and Secondary Treatment of Craniocerebral Wound. A. Arendt—p. 11.

*Papilledema in Craniocerebral Gunshot Wounds. A. N. Murzin—p. 47.

*Role of Histamine in Therapy of Various Forms of Pain Associated with Gunshot Wounds of the Peripheral Nervous System. I. I. Rusetskiy—p. 70.

Papilledema in Craniocerebral Gunshot Wounds—Murzin observed edema of the optic disk in 60 per cent of all cases of craniocerebral wounds. This symptom is significant in diagnosis, since it indicates a progressive intracranial hypertension possibly requiring immediate surgical intervention. Infection of the wound or an infectious process developing as a result of foreign bodies (metal or bone fragments) in the brain are the chief causes of papilledema. Gunshot wounds of the parietal and occipital region are more frequently associated with choked disk than are injuries of the frontal lobe. Since papilledema rarely occurs in cranial wounds without penetration of the dura it may aid in differential diagnosis of the type of wound. Murzin suggests that the term "edema of the optic nerve" be used in cases in which it is difficult to differentiate between congestive and inflammatory manifestations.

Histamine for Pain from Gunshot Wounds of Peripheral Nerves—Rusetskiy injected intracutaneously 2 to 3 drops of a 1,000 solution of histamine hydrochloride in 60 cases of peripheral nerve injuries associated with painful syndromes. In the majority of cases there was a temporary analgesic effect lasting from three to six hours. Preservation of some degree of sensitivity in the area of injection was a prerequisite for this therapeutic action. Histamine injections at a distance from the painful zones had no effect. When the injections were repeated at frequent intervals the analgesic effect became weaker and of shorter duration. Less concentrated solutions of histamine proved ineffective. In pain syndromes associated with vascular spasm, histamine injections not only relieved the pain but produced a prolonged dilatation of the cutaneous capillaries of the painful zone. The mechanism of the analgesic action of histamine is dependent on neurohumoral reactions developing in the organism. There is no inhibition or weakening of sense perceptions. The painful area of the skin responds to sensory stimuli in the same way as before the injection. Rusetskiy emphasizes the need of further research on the problem of relief of pain connected with peripheral nerve injuries, in view of the frequency of this type of injury in war.

Book Notices

War Gases Their Identification and Decontamination By Morris B. Jacobs Ph.D. Cloth Price \$3 Pp 180 with 8 illustrations New York Interscience Publishers, Inc 1942

In the event of a poison gas attack on civilians, vigorous preventive action by local defense authorities must be taken. Although those already gassed will be cared for by physicians, the gas identification officer, the decontamination officer and the health officer must speedily identify the chemicals involved, mark off contaminated areas and issue such information as will prevent further casualties from occurring, allay fear and in general guide medical treatment. Dr. Jacobs has prepared the present volume to provide these officers with "a system for the detection, the sampling and the identification of the chemical warfare agents, and the decontamination of areas and materials polluted by them." This highly technical material is presented in short textbook form accurately and concisely yet with much valuable factual information. The inclusion of numerous tables, diagrams and references is helpful. Although the book is not intended primarily for the physician, it contains many data on the toxicity and fundamental chemical reactions of the war gases that will be useful to him.

Growing Up in a World at War Paper No pagination Chicago Institute for Psychoanalysis 1942

This pamphlet is a report of a group of child psychiatrists and psychoanalysts, members of a committee on psychologic problems of children in wartime. The purpose was to present an analysis of the probable important effects of the war on children and the effect on their character development. Children's reactions to any fearful situation are dependent on their earlier life experiences and the emotional stability of the parents. The reaction to war may mean for the child insecurity based on reopening of old anxiety or on change in the child's environment or may be dependent on transmission to the child of the parents' feelings of insecurity.

The children observed showed defenses against the anxiety provoked by the war characteristic of the age and personality makeup of each child. These defenses, such as talking about the war, bragging, depreciation of the enemy and denial of danger, are discussed. Some of these are recognized to be wholesome defenses and some potentially harmful to the child's growth. Children of preschool age up to 5 or 6 years are particularly sensitive to the attitudes and feelings of those about them. While fears for these children center primarily about fear of separation from their parents they are reinforced by specific anxiety producing situations they have already experienced. The unknown is terrifying for children, and much anxiety is occasioned in this youngest group by their lack of understanding of the situations they have discussed.

The grade school children seem somewhat less vulnerable than the younger children. While faced with the same basic anxieties as are found in little children, they are preoccupied with achievement in academic and physical skills and tend to visualize dangers in more explicit terms than do the younger children. They are curious about the war but feel emotionally somewhat detached from the war threat unless separation from the parents or parental anxieties intrude. Children of this age are particularly eager to participate in activity of aid in the war.

For the adolescent, wartime conditions are particularly disturbing. For him the insecurity present in children of all ages takes the form of anxiety for his future, his schooling, his career. Natural resistance to authority evidenced by adolescents is greatly accentuated. Interruption of schooling and opportunity for employment disrupt the peacetime controls. The greatest danger to the adolescent, as has been true in England, is delinquency. This is not a wartime problem primarily, but for adolescents the shift of peacetime values to the permissiveness of wartime creates a new burden under which it is more difficult to maintain equilibrium.

This pamphlet is directed to teachers, social workers and group leaders as well as to parents. The planning suggested is based on an interest to avert development of neurotic reactions, character breakdown and delinquency.

The Aromatic Amino and Nitro Compounds Their Toxicity and Potential Dangers A Review of the Literature By W. F. von Oettingen Principal Industrial Toxicologist U. S. Public Health Service. From the Division of Industrial Hygiene National Institute of Health. Prepared by direction of the Surgeon General Federal Security Agency U. S. Public Health Service. Public Health Bulletin No. 271. Paper. Price 25 cents. Pp. 221 with 5 illustrations. Washington D. C. Supt. of Doc. Government Printing Office 1941.

The extraordinary development of war industries in recent months has brought into sharp focus the need for detailed knowledge of the toxicology of the manifold chemical compounds used in present day manufacturing. In the present emergency many materials are being used both as solvents and as starting materials for chemical synthesis which have not been carefully scrutinized for possible deleterious action on workers. The hazard involved in the use of these compounds is enhanced by the pressure for production, which tends to minimize the use of peacetime precautions in the now crowded plants. Furthermore, certain solvents, degreasers and chemical reagents which had been restricted in use because of proved toxicity have appeared again because appropriate substitutes are not available in quantity.

Under these circumstances the present compilation of data on the aromatic amino and nitro compounds is peculiarly welcome. Published as a public health bulletin, this summary embodies a wide range of facts. In many cases the chemical formulas, solubilities and chemical properties of the series of compounds under discussion are given, with a synopsis of the method of manufacture and the industrial processes for which they are employed. Methods of detection and analysis are given. The effects on animals are cited, with reference to the literature, from which toxic doses or lethal concentrations of vapor are tabulated. The symptoms and signs of poisoning in man are discussed, and in some instances appropriate treatment is outlined.

Among the aromatic amino compounds included are alkyl and aryl substituted derivatives of aniline, e. g. methylaniline, acetanilid and its derivatives, halogen and nitrated aniline compounds, paraphenylenediamine, and other derivatives of benzene or phenylenediamine. The large group of toluene, xylene and phenolic compounds follows. Next nitrobenzene, chlorinated nitrobenzene, nitrated toluene (e. g. trinitrotoluene), nitrated xylene and nitrated phenols are discussed. Of special interest are the sections on trinitrophenol (picric acid) and on phenylhydrazine. Finally various naphthalene compounds are considered such as diamino derivatives of naphthol.

There are frequent tables and several good graphs showing comparative toxicity at various dosage and concentrations. There is a bibliography of nearly seven hundred references filling some twenty-nine additional pages.

This compact and concentrated compendium will prove invaluable to safety committees in large plants and to industrial physicians. It should be on hand in every state health laboratory and similar municipal institutions or offices of insurance appraisers. In medical schools, particularly in relation to courses on public health and industrial medicine, the bulletin will be especially welcome.

Surgical Pathology By William Boyd M.D. LL.D. M.R.C.P. Professor of Pathology University of Toronto Toronto. Fifth edition. Cloth. Price \$10. Pp. 843 with 320 illustrations. Philadelphia & London W. B. Saunders Company 1942.

This edition contains many improvements in text and illustrations over the previous one. Numerous new subjects have been added. The author appropriately devotes chapter 1 to a discussion of the importance of pathology to surgery. He calls attention to the fact that the material seen in the necropsy room is far different from the pathologic material seen in the operating room, since the former represents disease in its late stages whereas the early stages of disease are observed in the operating room. The author therefore correctly implies that surgical pathology is different from pathology but emphasizes that the surgeon or surgical pathologist must first be grounded in the science of pathology. The text reads smoothly, it is readily understandable and is devoid of complicated terms and classifications. For that reason the volume is appropriate for students' use. The early chapters particularly are examples of this simplicity and freedom from complicated discussion.

Although the text in general is an expression of the author's experiences and opinions, he has not failed to include the opinions of others, thereby he has been able to keep his material up to date. For example, in cholecystitis he correctly considers bacterial inflammation of secondary importance to chemical inflammation which he believes is the instigating lesion in gallbladder disease. Moreover, Batson's theory of the spread of carcinoma is given credence and Langley's theory criticized as being wholly inadequate. Strictures of the rectum are correctly ascribed to venereal lymphogranuloma and not to syphilis.

Naturally the description of certain lesions is not as concise and accurate as the description of others. For example the author's use of various terms in the discussion of certain types of goiter is disappointing. Although he occasionally uses some of the terms adopted by the American Association for the Study of Goiter many years ago he fails to adhere to that classification which describes the different types of goiter adequately. Many surgeons indeed would take exception to his statement on page 311 that local excision of malignant polyps of the rectum is sufficient. Although there is a total lack of agreement among surgical pathologists as to the classification to be used for chronic cystic mastitis the reviewer has encountered many descriptions and classifications which might be considered more expressive of the various lesions found in that disease. However, the inadequacies in this textbook are so infrequent that they are overshadowed by the fine points. It may correctly be considered an authoritative treatise on surgical pathology and is particularly adapted for use by the student.

Medical Manual of Chemical Warfare [including also] An Atlas of Gas Poisoning. Reprinted by Permission of the Controller of His Britannic Majesty's Stationery Office. Revised edition. Cloth. Price \$2.50. Pp. 108 with 5 illustrations. 15 with 10 illustrations. Brooklyn Chemical Publishing Company Inc. 1942.

This manual is a British official release on the first aid procedures for and later treatment of war gas casualties. Its value is much enhanced by the inclusion in color of plates from "An Atlas of Gas Poisoning, London, 1918 and 1937, illustrating typical 'blue' and 'gray' cases of suffocant gassing and classic vesicant lesions of the skin and eye. The text is unusually complete for a manual, yet the work has lost none of its force: the result chiefly of accurate writing, emphasis on essentials and large print. It must be remembered that knowledge of the treatment of war gas casualties, like the knowledge of the treatment of other injuries, is not static. Thus any manual tends to become out of date. The British have attempted to remedy this by issuing amendments from time to time. The usefulness of the manual is impaired unless these are at hand for reference. British thought has had considerably longer than has ours to crystallize on matters of chemical warfare defense, and this is reflected in this manual. It is heartily recommended. The first American edition of "Medical Manual of Chemical Warfare" published by the same company in 1941, is much handicapped by its less attractive print, black and white illustrations and high retail price.

Developmental Aphasia in Educationally Retarded Children. An Examination of the Thesis that the Core of Backwardness in the Primary School is so far as This is not due to low Mental Capacity is Provided by Aphasic Characters of Learning Interference. By M. MacNeehan, M.A., B.Ed., Ph.D. Department of Psychology, Edinburgh University. Edinburgh: Publications of the W. H. Ross Foundation (Scotland) for the Study of Prevention of Blindness II. Paper. Price 3s. Pp. 95 with 46 illustrations. London: University of London Press Ltd. 1942.

The author has produced an excellent summary on developmental aphasia, a term covering the various types of psychologic disorders which are commonly known as word blindness, word deafness, speech disorders, speech delay and apraxia. He analyzes the syndrome in considerable detail and studies a group of 140 retarded children by means of the Terman-Merrill revision of the Stanford-Binet scale and a number of tests of language attainment, as well as tests of laterality and squint. The author devotes many pages to graphs, tables and charts showing psychologic characteristics such as reading and spelling accomplishments, relationship of retardation to learning interference and eye dominance as related to learning interference of both a qualitative and a quantitative nature. The author's conclusion is that the problem of retardation in children due to interference in language learning has a high relationship with left laterality of the eye and some relationship to left

handedness and squint according to either left or right eye dominance. A good deal of learning interference, he says, is not due to "lack of capacity" but is related to a "functional confusional pattern." His data would seem to bear out this conclusion fairly competently.

Memoranda on Medical Diseases in Tropical and Sub Tropical Areas. Reprinted by Permission of the Controller of His Britannic Majesty's Stationery Office. By Command of the Army Council. Great Britain War Office. First American edition. Cloth. Price \$4.75. Pp. 282 with 108 illustrations. Brooklyn Chemical Publishing Company Inc. 1942.

This is a military manual of essential material needed during special emergencies. Its table of contents includes most acute diseases which are or may be of importance in hot climates including smallpox, trench fever and typhus fever. It is an excellent practical summary of great value for physicians facing unfamiliar disease problems in warm climates. It is especially strong on control methods. It will be of limited value for American civilian and military physicians. More in detail, the chapter on malaria is a condensed manual of much value. Pelagra is not discussed. There is a tendency to present outmoded and alternative theories which might well be expurgated. Based on British army experience the discussions are not adequate in many fields where American work is preeminent, as in the food deficiency diseases, typhus group and amebiasis. In the case of amebiasis for instance, too many drugs are recommended on the basis of authority and custom rather than on the basis of objective experience and scientific evaluation of their toxicity and action. Probably the most important diseases from a military standpoint in the field are malaria, dysentery and typhus fever. A broader as well as more specific discussion of the last mentioned would be an improvement. Malaria and dysentery are well covered. The illustrations are excellent, as is also the selection of temperature charts and the comprehensive index. The statement under dysentery could well be extended to evil practice: "Any medical officer not submitting the stools of his dysentery patients for laboratory examination, where facilities for such exist, is guilty of criminal negligence." The small but legible type allows a surprising amount of material to be presented.

Homenaje al Profesor Pedro Belou de sus ex colaboradores y miembros del personal docente y tecnico del Instituto de anatomia y la Cátedra de anatomia descriptiva de la Facultad de ciencias medicas de Buenos Aires on el 28. ano de su ejercizio docente en la Cátedra Universitaria. Paper. Pp. 467 with illustrations. Buenos Aires: Guillermo Kraft Ltda. 1941.

This book was prepared in homage to Dr. Pedro Belou by his collaborators and the group of technicians and instructors of the Institute of Anatomy and the first chair of descriptive anatomy of the Faculty of Medical Sciences of the University of Buenos Aires. It was presented to Dr. Belou on the twenty eighth anniversary of his teaching in the chair of anatomy of the faculty. The book contains several articles of Dr. Belou which were read before medical societies and have not been previously published. It contains also news items in several medical journals of our hemisphere and of Europe concerning lectures, trips and some other medical activities of Dr. Belou, as well as reproductions of speeches in his honor. There are several pictures of Dr. Belou from childhood to his present age, pictures of scenes during ceremonies in his honor and of honorary diplomas given to him in various countries. There is a large section of bibliography of Dr. Belou's work. The larger part of the book is dedicated to the morphology of the arterial system, to which subject Dr. Belou has devoted a large part of his activities.

Recent Advances in Pathology. By Geoffrey Hadfield, M.D., F.R.C.P., Professor of Pathology in the University of London and Lawrence P. Garrod, M.A., M.D., B.Ch., Professor of Bacteriology in the University of London. Fourth edition. Cloth. Price \$5.50. Pp. 346 with 35 illustrations. Philadelphia: Blakiston Company. 1942.

The advancement of our knowledge of disease and its effects on the human body has made necessary discussions of the vitamin deficiency diseases, essential hypertension and some of the problems related to war, such as the crush syndrome. So rapid however has been the progress of problems related to the war that one finds no discussion whatever of blast. There are accounts of new investigations in the field of cancer research, rheumatic fever and pneumonia.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

COLD ALLERGY WITH NASAL SYMPTOMS

To the Editor—What can be done for a woman aged 38 with a "cold and moisture allergy" whose general physical and head examinations are entirely negative? On exposure to cold moist air she immediately develops a congestion of the nasal membranes—probably due more to moisture than to cold as dry frosty weather does not bother her much. Physical examinations, roentgenograms and nasal examination in warm dry weather are entirely negative. There are no protein allergies and there is no family history of any. The tonsils are out. Nasal lavage and mild protein silver packs do not help in the least. Nothing in her surroundings appears to contribute to her condition.

M D, Pennsylvania

ANSWER—It is questionable whether there is any difference between allergic nasal responses to cold air or to cool humid air—both are undoubtedly instances of cold allergy. Any one of several measures may prove successful in the management of this condition. Daily cold showers, followed by warm if the reaction is too severe, may create a tolerance. Tub baths, the temperature of which is reduced daily, may also be effective. Some clinicians have employed ice rubs to the chest, followed by heat application if necessary. The latter form of treatment may be rather hazardous. A simple method for increasing tolerance to cold consists in immersion of both hands and forearms in cold water (about 45 F) for about four minutes twice daily. In some instances injections of histamine have been of considerable help in relieving the condition. They should be given twice daily at first, beginning with a dose of about 0.1 cc. of a 1 to 5,000 solution and increasing it until a maximum dose of about 0.2 to 0.3 cc. of the 1 to 1,000 solution is reached. After about a two week schedule of bi-daily doses the injections may be given daily and finally twice weekly.

DISEASES FROM DOGS AND CATS

To the Editor—Recently I have been asked by several persons about the advisability of having cats and dogs as pets in a household where there are babies and younger children. Could you give me any references on the subject and perhaps a list of diseases that are carried by dogs and cats?

H R Fishback Jr MD Albuquerque N M

ANSWER—Rabies is the most serious of the afflictions which can be charged against the dog. Leptospirosis is becoming an increasing problem in dogs, with human infections by both *Leptospira icterohemorrhagiae* and *Leptospira canicola*.

Animal parasites which infest most dogs form somewhat of a menace to man. The most dangerous is *Taenia echinococcus*, which carries on its adult stage of life in the intestine of dogs while its larval stage is spent in the tissues of man or other animals. Another tapeworm which should be mentioned is *Dipylidium caninum*. Its larval stage occurs in lice and fleas which infest dogs, children becoming infected by accidentally swallowing such lice and fleas or crushing them and afterward sucking the fingers. The guinea worm, *Dracunculus medinensis*, has been found in both dog and man, while several flukes of dogs may be transferred to persons. Three forms of mange afflict dogs, only one of which is transmissible to man—sarcoptic. Among the four forms of ringworm from which dogs suffer, a rare case is passed to persons.

Dogs may become infected with various bacterial diseases from other animals but do not form a serious menace to man. Tuberculosis is contracted sometimes from association with tuberculous persons, from drinking infected cow's milk or from the offal of slaughter houses. Anthrax and glanders are sometimes contracted by dogs from eating animals that have died of those diseases. Infection with foot and mouth disease is difficult, as it is also with trichinosis. Dogs are not generally susceptible to the rodent diseases, but they may act as mechanical carriers of rat bite fever, in which infection has followed the bite of a dog which had recently fed on an animal dead of the disease. The same is possible with other rodent diseases. Sporotrichosis of dogs probably is only a slight menace to man. Rocky Mountain spotted fever infects dogs, while boutonneuse fever, which is closely related to spotted fever, finds its chief reservoir in that animal.

Dogs have been reported susceptible to the organism causing scarlet fever, and free access of a dog to a human case of the disease might be a menace to children.

Cats are fairly resistant to many of the human diseases. On rare occasions they have been found tuberculous from infected milk or meat. They are susceptible to glanders but rarely contract the disease naturally. They may become infected with rabies from contact with rabid dogs, forming a serious menace to children. Cats are hosts of several animal parasites, some of which are transferable to man. The liver fluke, *Opisthorchis felinus*, is common in Europe, while the closely related species *Opisthorchis pseudofelinus* is found in central parts of the United States. Both parasites are natural inhabitants of the cat from which man is infected. The intestinal flagellate *Giardia* found in rats and mice is a variety of the human species, and cats have been found responsible in disseminating the infection. The dog tapeworm *Dipylidium caninum*, is harbored by cats also. Cats are relatively immune to the rodent diseases. They show slight susceptibility to plague and to tularemia but are relatively unimportant in the spread of each disease. Several instances are recorded in which rat bite fever followed the bite of a cat, but probably the cat was a mechanical carrier of the spirochetes picked up from eating an infected rat. While the relation of cats to diphtheria is a disputed point, Simmons reports two cats from which he obtained diphtheria bacilli. Cats may harbor the spirochetes of leptospirosis.

PEPSIN CHEWING GUM AND STOMACH ULCER

To the Editor—Has any work been done on the question of the pepsin in so called pepsin chewing gum in relation to gastric and duodenal ulcers? Does chewing gum actually contain pepsin, and if so does the amount added to the stomach from chewing such gum have any effect on ulcer?

George N Hasford, MD San Francisco

ANSWER—As far as can be determined, no work has been done on the effect of pepsin chewing gum on gastric and duodenal ulcers. The tentative standards of identity discussed by the chewing gum industry with the Food and Drug Department about three and a half years ago contained the following statement:

Pepsin chewing gum contains not less than 0.15 per cent by weight of U S P Pepsin, the proteolytic activity of which has not been impaired in the process of manufacture of the chewing gum."

As far as is known, substantially all of this pepsin is chewed out of the gum within a few minutes and swallowed.

In view of the high peptic activity of the acid gastric juice present in patients with gastroduodenal ulcer, it is apparent that the pepsin content of chewing gum is too small to affect the course of the ulcer process.

It may be stated also that the increased amount of saliva secreted during the chewing of gum would tend to exert a neutralizing action on the acidity of the gastric juice and therefore reduce its peptic activity. Although the buffer capacity of "resting" saliva is low, the buffer capacity of saliva is increased considerably during active secretion. Resting saliva is stated to have a pH of 6.6, the pH may rise to 7.5 during profuse secretion. These values obviously are higher than those of acid gastric juice, which range usually from 1 to 2. Drs Alexander Rush and A B Luckhardt (unpublished observations) have found that the swallowing of large amounts of saliva definitely decreases the acidity of the gastric contents obtained after histamine stimulation.

RIDGED FINGERNAILS—YELLOWING OF GRAY HAIR

To the Editor—Is there any agreement as to the cause of ridging in the finger nails which gives them a washboard appearance? Is this considered nutritional in origin? The patient is 68 years of age and is otherwise well. Is there any relation between this condition and the tendency for gray hair to assume a yellowish tinge?

R J Jackson, MD, Rapid City S D

ANSWER—Cross furrows and ridges in the finger and toe nails are among the commonest deformities of these structures. They may follow any accident, fever or other disturbance of health, appearing a short time afterward. Zeisler (Trophic Dermatoses Following Fracture, *J Cutan Dis* 16:305 1896) gives an interesting account of his own experiments with Beau's lines. In a symposium on diseases of the nails at the twenty-fifth annual meeting of the American Dermatological Association the same author (*Transactions of the American Dermatological Association for 1901*, p 126) lists as causes typhoid and typhus fevers, severe gastrointestinal disturbances, pneumonia, erysipelas, epididymitis, angina, parotitis, scarlet

fever, measles, influenza, acute rheumatitis and severe general trauma, 'even the normal puerperium and sea sickness seem to have caused it occasionally'. During the discussion Hartzell (p 140) reported Beau's lines after a few days of sea sickness and Bulkley (p 141) stated that he had seen a case of alopecia areata showing finger nail ridges which began simultaneously with the alopecia. Ormsby (Diseases of the Skin, ed 5, Philadelphia, Lea & Febiger 1937 p 1267) mentions that Hyde told of the occurrence of Beau's lines after attacks of dyshidrosis. They are not ordinarily considered of nutritional origin, but spoon nails, another trophic disturbance that might be confused with the cross ridges, are often associated with severe anemia.

The yellow tinge assumed by gray hair in some persons has no relation to the cross furrows of the nails. The yellow hair color is a natural phenomenon connected in some persons with graying of the hair. In bleaching hair, according to Redgrove and Foan (Hair Dyes and Hair Dyeing Chemistry and Technique, ed 2, London, William Heineman, 1939, p 182), it is found that red or blond hair is much more likely to remain yellow than hair of darker shades which will bleach to white more readily. The only recourse seems to be the skilful application of bluing, to counteract at least to a degree the yellow tinge. This is the advice of Redgrove and Foan, who infer from this characteristic of blond and red hair that there are at least two kinds of melanin in human hair. Those who have investigated the chemical characteristics of the pigment of human hair are in agreement with this opinion (Arnow, L. E. The Acid Soluble Pigment of Red Human Hair, Biochem J 32 1281 [Aug] 1938).

TREATMENT OF CHRONIC GONORRHEAL ARTHRITIS

To the Editor.—Can you give me any information on the treatment of gonorrhea with heat therapy or any other suggestion for treating chronic gonorrheal arthritis?

J. Kimber LeVon M.D. Carlisle Pa.

ANSWER.—It is most important to establish first that the patient is suffering from chronic gonorrheal arthritis and not chronic rheumatoid arthritis with an associated unrelated gonococcal infection. If the patient's history, physical examination and laboratory findings are consistent with a diagnosis of chronic gonorrheal arthritis, he can be treated in one of several ways.

Sulfathiazole, 4 Gm initially and 1 Gm every four hours day and night. The fluid intake should be constant and sufficiently great to insure a twenty-four hour urinary output of 1,500 to 1,800 cc. A daily fluid intake of 2,500 to 3,500 cc is usually adequate. If the patient is to respond to sulfonamide therapy, one should observe real evidence of improvement within three to four days.

If the patient fails to improve under this form of therapy, one can then employ either fever therapy or fever therapy in conjunction with sulfonamide therapy, the latter being the more effective. Fever therapy can be administered in one or two ways: (a) by means of radiant energy or (b) by means of typhoid vaccine intravenously. The instructions to be employed in these two forms of treatment are listed.

FEVER PRODUCED BY RADIANT ENERGY

(The treatment is the same for patients not receiving sulfathiazole except that the drug is omitted.)

1 The patient should receive sulfathiazole 1 Gm every four hours day and night for the preceding three days.

2 Administer 15 to 20 Gm of salt daily for the two days before the fever therapy is to be administered.

3 Fever therapy

(a) Light breakfast. One Gm of sulfathiazole, to be repeated every four hours.

(b) Morphine sulfate $\frac{3}{4}$ to $\frac{1}{4}$ grain (0.01 to 0.015 Gm) hypodermically and sodium amytal $1\frac{1}{2}$ to 3 grains (0.1 to 0.2 Gm) by mouth before placing the patient in the fever therapy box. The dose of drugs used will depend on the size of the patient. The morphine or other opiate can be repeated every two to three hours if necessary.

(c) Take temperature, pulse and blood pressure every fifteen minutes.

(d) The aim is to produce a temperature between 106 and 106.5 F and maintain it for the desired period of time.

(e) Allow liquids (at room temperature) as desired. Encourage the patient to drink as much as 1 per cent saline solution or orange juice containing 1.5 per cent saline solution in order to prevent serious salt and water depletion. The fluid intake should be at least 5,000 cc the day of treatment. When the

procedure is finished, 1,500 to 2,000 cc of isotonic solution of sodium chloride intravenously may or may not be indicated.

(f) If necessary, apply an ice bag to the head.

(g) A medical officer should always be in attendance or at hand.

FEVER THERAPY INDUCED BY MEANS OF TYPHOID VACCINE INTRAVENOUSLY

(The treatment is the same for patients not receiving sulfathiazole except for the omission of the drug.)

1 The patient should receive sulfathiazole 1 Gm every four hours day and night for the preceding three days.

2 Administer 15 to 20 Gm of salt daily for the two days before the fever therapy is to be administered.

3 Fever therapy schedule

(a) Light breakfast. One Gm of sulfathiazole, to be repeated every four hours.

(b) Following this place the patient in bed between woolen blankets. Keep the patient completely covered except for the head and neck.

(c) Place four hot water bottles (140 to 150 F) in the bed. These should be replaced every thirty minutes throughout the day care being taken not to uncover the patient when they are changed.

(d) Sodium amytal or some similar barbiturate preparation $1\frac{1}{2}$ to 3 grains by mouth depending on the size of the patient.

(e) Morphine or other opiate hypodermically, depending on the size of the patient.

(f) After the patient has been in the warm bed for one hour administer triple typhoid vaccine (50 million organisms) intravenously.

(g) Take temperature and pulse every fifteen minutes.

(h) Take blood pressure every fifteen to thirty minutes.

(i) If the temperature is not above 102 F within two hours give another 50 to 100 million organisms intravenously. This can be repeated again in another hour or two if necessary. The aim is to produce a temperature of 105 to 106 F and maintain it as long as possible. Once the peak temperature is reached it can usually be sustained provided the hot water bottles are changed regularly and without uncovering the patient.

(j) The opiate may be repeated every two to three hours if necessary.

(k) Allow liquids (at room temperature) as desired. Encourage the patient to drink as much 1 per cent saline solution or orange juice containing 1.5 per cent saline solution in order to prevent serious salt and water depletion. The fluid intake should be at least 5,000 cc on the day of treatment. When the therapy is completed, 1,500 to 2,000 cc of isotonic solution of sodium chloride intravenously may or may not be indicated.

(l) If the patient is too restless or has a headache, apply an ice bag to his head.

(m) A medical officer should always be in attendance or at hand.

SULFANILAMIDE ADDED TO TALCUM POWDER IN RUBBER GLOVES

To the Editor.—Recently during an operation one of my gloves was pricked with a needle and the talcum powder was spattered in the wound. Would it be harmful to the surgeon to add a small amount of sulfanilamide to the talcum powder? What percentage of sulfanilamide would give an additional safety factor to the doctor and the patient if the glove is punctured during an operation? Have there been any studies made on this problem?

Harry Kirschbaum M.D. Detroit

ANSWER.—There have not been studies on this problem reported. Possibly 10 per cent sulfanilamide added to the talcum powder might give protection to the surgeon. It is almost certain that this would not give protection to the patient.

SKIN REACTION FOLLOWING IRRADIATION

To the Editor.—On page 1262 of The Journal for Dec 12, 1942 there is an item on Treatment of Recurrent Hyperthyroidism. I think that the following statement is incorrect. Moreover there is some danger of burning the skin which may happen under the most carefully controlled circumstances referring to the use of x-ray irradiation in the treatment of hyperthyroidism. The term burning of the skin should not be used when referring to a skin reaction following irradiation. The careless use of this term is a cause of many damage suits. Reaction is an accurate term and is preferable. The statement that there is danger of burning the skin is misleading because only relatively small doses of x-rays are usually required in the treatment of hyperthyroidism and with the proper control of dosage there should be nothing more than a mild skin reaction.

PHYSIOLOGIC CONSIDERATIONS IN THE TREATMENT OF PORTAL CIRRHOSIS

CARL H. GREENE, M.D.
NEW YORK

The main clinical characteristics of portal cirrhosis are well known. It is most frequently seen during the fifth and sixth decades, the average age being close to 50 years (table 1). Men are more frequently affected than women, the proportion being approximately three to one. The results of a study of 108 cases seen at the New York Post-Graduate Hospital (table 2) were very similar to those reported recently from New York by Patek and Ratnoff,¹ by Fleming and Snell² at the Mayo Clinic and by Wayburn and Guerard³ from San Francisco. These studies in turn do not differ greatly from the earlier reports of Wickham Legg,⁴ Murchison⁵ and Rolleston.⁶

Clinical studies regarding the pathogenesis of this condition are equivocal. The history of the abuse of alcohol is a frequent but not essential finding. Syphilis was present in about one sixth of the cases reported. This is a much smaller proportion than that noted in some of the earlier studies. Rolleston⁶ in the first edition of his classic work reported that syphilis was considered to give rise to lesions quite different from those of portal cirrhosis. In the last edition,⁷ published twenty-four years later, he quotes various authors as finding a positive Wassermann reaction in from 40 to 80 per cent of cirrhotic patients.

Clinical evidence as to the pathogenesis of cirrhosis is not as conclusive as is some of the experimental evidence. The older literature has been reviewed by Moon,⁸ who points out that numerous agents, diverse in character, are capable of causing degeneration and necrosis of hepatic cells. The continued or repeated action of these agents results in the production of

chronic diffuse hepatitis as indicated by degeneration and necrosis, parenchymal regeneration and proliferation of fibrous tissue.

A few agents,⁹ including the chlorinated hydrocarbons, especially chloroform and carbon tetrachloride, inorganic poisons such as phosphorus, arsenic and selenium,¹⁰ other chemical compounds, especially the tars, and some bacterial infections, are accepted on both clinical and experimental grounds as capable of producing cirrhotic changes in the liver.

The role of alcohol is still indeterminate. Connor¹¹ in particular has emphasized the importance of the fatty infiltration of the liver so frequently noted in alcoholic addicts especially when the excessive intake of alcohol is associated with an insufficient diet. Prolonged fatty infiltration of the liver gradually produces a progressive perilobular fibrosis and eventually a true portal cirrhosis.

This literature dealing with the relation of the liver to fat metabolism has been reviewed recently by several authors.¹² Many different factors acting either singly or in combination may produce an increase in the amount of fat in the liver. A high fat diet, for example, will produce a permanent increase in contrast to the temporary increase produced by fasting. The chronic fatty infiltration of the liver reported in pancreatectomized dogs and some patients with diabetes is well recognized. Extracts of the anterior pituitary will produce a fatty liver. It is generally accepted that an undue increase in the amount of fat present in the liver will contribute to the development of cirrhosis.

Conversely, an increase in the amount of protein or carbohydrate in the diet usually decreases the amount of fat in the liver. Choline, pancreatic extract or lipocaine will prevent the accumulation of fat due to a high fat diet and so prevent the development of cirrhosis.

Evidence is being accumulated that dietary factors other than the relative amounts of carbohydrate, protein and fat in the diet affect the liver. Gyorgy and Goldblatt¹³ observed that when young rats were kept on a diet devoid of vitamin B but supplemented with thiamine, riboflavin and pyridoxine they showed evidence of hepatic injury. This consisted primarily of

acute diffuse necrosis with fatty infiltration. In some instances considerable periportal fibrosis was observed. Rats fed on the same basal diet supplemented with yeast or yeast extract did not show pathologic changes in the liver. Shortly afterward, Rich and Hamilton¹⁴ reported the development of cirrhosis of the liver on a nutritional basis in rats, while Spellberg, Keeton and Ginsberg¹⁵ made similar observations in guinea pigs. In both studies the addition of yeast to the diet prevented the development of the changes in the liver. The earlier studies of Curtis and Newburgh¹⁶ and others had shown that an excess of cystine in the diet would produce acute hepatic necrosis. Studies by Gyorgy, Poling and Goldblatt¹ and Blumberg and McCollum¹⁸ showed that the addition of extra cystine to the experimental diet of rats accentuated the development of cirrhosis. Yeast or choline prevented the cirrhosis even though extra cystine was fed. Similar results are reported by Lillie, Daft and Sebrell,¹⁹ who produced cirrhosis in rats by the use of a diet low in protein and fat with added cystine. The cirrhosis was prevented by feeding choline, methionine or casein either singly or in combination. Supplying 20 per cent alcohol to the rats in place of drinking water apparently had no influence on the results.

Closely related to the studies of the production of cirrhotic changes in the liver by dietary means are the studies of the effects of diet on the production of experimental cancer of the liver. It is now known that many chemical compounds have carcinogenic properties.²¹ The first changes in the liver of a rat on this carcinogenic regimen are necrosis and fibrosis suggestive of cirrhosis. The characteristic hepatoma develops later. Deficient diets similar to those producing cirrhosis render the animals more susceptible to cancer of the liver.²² The addition of dried liver, yeast, riboflavin and casein, methionine or choline to the diet, on the other hand, has a protective action.

While the experimental production of cirrhosis of the liver by dietary means now is an accepted fact, the factors responsible are still a source of debate. Many of the diets produce a fatty infiltration of the liver, and the cirrhosis has been ascribed to this. The protective action of choline is cited as confirmatory evidence for this view. On the other hand, the liver is concerned in the absorption, storage and utilization of the various vitamins. Rhoads has stressed the importance of the vitamins, especially those of the B complex, for the maintenance of normal structure and function of the hepatic parenchyma. Supplementing deficient diets by casein, yeast and liver or their extracts had a protective effect. The role of vitamin deficiency in the production of cirrhosis therefore, has been stressed.

The relative importance of these two factors of excess fat and vitamin deficiency in the production of cirrhosis is not established at the present time, but their importance in treatment has been established.

Goodhart and Jolliffe²³ administered large doses of vitamin B to a series of alcoholic polyneuritis patients with good results. Several of the patients had hepatic cirrhosis, and they noted a coincident improvement in the general condition of the patient as well as of the polyneuritis. Patek and Wryburn and Guerard also reported small series of cases showing improvement on vitamin therapy.

More extensive studies have been reported by Patek and Post and by Fleming and Snell. The former used a diet of protein 139, fat 175 and carbohydrate 365 Gm with a caloric intake of 3,591. Fifty Gm of powdered brewers' yeast daily was included in the diet. In addition to the yeast the patients received intramuscular injections of concentrated liver extract 5 cc twice weekly and of 5 mg of thiamine hydrochloride daily.

Fleming and Snell used a diet of from 350 to 500 Gm of carbohydrate, 110 Gm of protein and approximately 50 Gm of fat. The protein was chiefly of vegetable origin or derived from milk or egg white. This diet was supplemented by various vitamin preparations such as 30 minims (2 cc) of oleum percomorphum and 9 to 12 ounces (265 to 355 cc) of orange juice or 100 mg of ascorbic acid daily. Liver extract was given either by mouth, 2 ounces (60 cc) daily or 2 cc of a liver extract intramuscularly three times a week. Thiamine hydrochloride, 4 to 10 mg daily, and two to four tablets of brewers' yeast were given with each meal.

23 Goodhart, Robert and Jolliffe, Norman. Effects of Vitamin (B₁) Therapy on the Polyneuritis of Alcohol Addicts. *J A M A* 110: 414-418 (Feb. 5) 1938.

While differing greatly in detail, the diets used by these two sets of investigators were alike in that they were high protein, high vitamin, high caloric diets. The protein was preponderately vegetable or of dairy origin. Patek and Post do not stress the point, but in their diet less than one fourth of the protein was supplied by meat. Yeast and liver extracts were used to insure an adequate supply of vitamins.

Both Patek and Post and Fleming and Snell report encouraging results in their series of cases. Not only was the clinical course of the disease influenced favorably but there was an increased period of survival in the treated groups of cases as compared to the control groups. It would seem, therefore, that a high protein, high vitamin diet is capable of favorably influencing the course of a portal cirrhosis presumably by favoring regenerative processes in the hepatic parenchyma. The reports are agreed that on such a diet many of these patients show slow but progressive improvement with the disappearance of ascites, gain in weight, strength and appetite and increase in serum proteins. The results are encouraging, but it must be remembered that the effects are slow. It takes time for the improvement in nutrition as well as for the regeneration of hepatic tissue to take place. Patek reports two months on the average before definite improvement becomes apparent. Fleming and Snell reported that there was very little difference between the mortality rates for the control and treated groups of cases during the first year.

The dietary treatment of patients with cirrhosis, therefore, represents only one phase of management of this condition. The typical patient reports to the physician with a distended abdomen, palpable spleen, dilated veins of the abdomen and considerable amount of ascitic fluid. It is frequently the discomfort produced by the latter that makes him demand systemic relief. This clinical picture, which is also described as the syndrome of portal hypertension, is well known. Two factors enter into this syndrome particularly with reference to the production of ascites. On the one hand there is the interference with the blood flow through the liver²⁴ as emphasized by Herrick,²⁵ McIndoe,²⁶ Wakim and Mann²⁷ and others. The presence of portal hypertension has been confirmed at operation by direct measurements of the portal pressure.²⁸ Because of the development of collateral circulation and so-called caput medusae in cases of cirrhosis, an attempt was made to study the venous pressure directly in the veins of the abdominal wall to see how far it reflects the portal pressure. It has been our experience that the venous pressure in the veins of the abdominal wall of patients with cirrhosis is higher than that in the antecubital veins of the same patient. However, following paracentesis the veins in the abdominal wall collapse and further studies were not possible, so that one must conclude that ascites produces a measure of interference with the venous flow in the abdominal wall. The venous dilatation, therefore, is not necessarily evidence of development of collateral circulation

Portal hypertension is only one factor in the development of ascites. Another factor is hypoproteinememia, particularly diminution in the albumin fraction of the serum in consequence of damage to the liver. It is now accepted that the more advanced the cirrhosis, the greater the chance of the patient having a reduction in the serum albumin. In severe involvement there is not only a reduction in the albumin but also a reversal of the albumin/globulin ratio. It is this change in the serum proteins which is responsible for the diagnostic value of the Takata-Ara test in cirrhosis. In addition to the reduction of serum protein there may also be changes in the osmotic pressure of the serum proteins, as suggested by Butt, Snell and Keys.²⁹

In the early stages of cirrhosis, ascites often is readily controlled by the use of mercurial diuretics especially when used with ammonium chloride or nitrate. In my experience the efficiency of the mercurial diuretics apparently varies with the difference between the protein concentration of the blood plasma and that of the ascitic fluid. The more advanced the cirrhosis

and the greater the reduction in the serum proteins, therefore, the less effective has been the response to mercurial diuretics.

Anemia frequently is present in cirrhosis. Under these conditions transfusion improves the general condition of the patient not only by combating the anemia but also by increasing the serum protein, which improves the response to the mercurial diuretics.

Paracentesis has long been recognized as the method of last resort in the control of ascites. When the hepatic damage is so pronounced that the ascites can be controlled only by repeated and frequent paracenteses, the patient tends to go down hill rapidly. Hale-White³⁰ was one of the first to suggest the serious prognostic import of paracentesis. It is true that some investigators have argued that paracentesis is without effect³¹ on the serum proteins or on the process of protein synthesis, though this is denied by Benedetti.³²

Recent studies of Post and Patek³³ suggest that protein synthesis, particularly that of serum albumin is more difficult for the damaged liver than for the normal one. When the protein content of ascitic fluid is under 1 per cent, considerable amounts can be removed without much gross loss of protein. On the other hand, tapping 3,000 cc containing 2 per cent of protein would make a loss of 60 Gm of protein, which is an appreciable quantity. We have tried in a few instances to prevent protein depletion through paracentesis by concentrating the ascitic fluid and reinjecting the concentrated protein solution intravenously. Severe reactions were encountered, and treatment did not prove to be practicable. Numerous investigators have shown the value of plasma infusions in correcting a deficiency of serum protein in a variety of conditions. Ascitic fluid, chemically, is very similar if not the same as serum, and it has been advocated for the treatment of shock.³⁴ We therefore tried paracentesis and the direct readministration of ascitic fluid. The results have been encouraging.

REPORT OF CASES

CASE 1—A machinist aged 61, first seen on Feb 5, 1939, had been a consistent alcoholic addict for many years. His father died of cirrhosis of the liver. Abdominal distention and epigastric distress were first noted about a month before admission.

Examination showed evidence of a moderate degree of malnutrition. The abdomen was considerably distended with evidence of fluid. The superficial abdominal veins were distended. Hemorrhoids were present. Vascular spiders were noted on the chest. The liver was palpated 3 cm below the costal margin and was hard and slightly irregular. There was pitting edema of the ankles.

He was placed on a high carbohydrate high vitamin diet with a restricted intake of salt. Ammonium chloride and potassium nitrate were given in addition. During the next two months he was given nine injections of 1 cc each of either salyrgan theophylline or of mercupurin without diuretic response. Nineteen days after admission a paracentesis of 3,750 cc was necessary, and four weeks later 24,000 cc was withdrawn.

6/1/39	6.1	2.2	3.9	

He was discharged from the hospital after this paracentesis but returned three weeks later and 17,000 cc was removed. Infusions of ascitic fluid were then started. During the following three weeks 5,100 cc of ascitic fluid containing over 150 Gm of protein was given intravenously. During this period the urinary output exceeded the fluid intake by 7,185 cc and he lost 19 pounds (8.6 Kg). At the time of discharge from the hospital June 1, 1939, he was free from ascites. The serum proteins were 85 per cent. Three years later, June 1, 1942, he was well, and the liver was large and firm 3 cm below the costal margin. The spleen was just palpable. The veins over the abdominal wall were not unduly prominent. There was no ascites. The serum proteins were 69 per cent.

CASE 2—A junk dealer aged 30 first came to the hospital in March 1941 because of flatulent indigestion. He had been decidedly alcoholic for many years. He was underweight and showed evidences of malnutrition. The abdomen was moderately distended, but no fluid was present. The spleen could not be felt, but the liver came down to the umbilicus. He left the hospital against advice the following day. In July frequent nosebleeds began and he noted an icteric tint to his sclera. He returned to the hospital in November with a slight icterus and pronounced ascites. Other findings were the same as before. The icterus quickly disappeared but the ascites increased progressively. The response to mercurial diuretics was unsatisfactory. On December 17 a paracentesis of 9,200 cc was done. Following the paracentesis there was a copious extravasation of fluid into the scrotum and back up to the axilla. This gradually was absorbed. Reinfusion of ascitic fluid was then started without outward reaction. On Jan 13 1942 a second paracentesis of 6,000 cc was necessary. In the following seven days he received 4,175 cc of ascitic fluid containing 138 Gm of protein intravenously. His weight dropped from 162 pounds (73.5 Kg) on December 23 to 144 pounds (65 Kg) on discharge. The serum proteins were albumin 28, globulin 42, total protein 70 on admission and albumin 37, globulin 47, total protein 84 on discharge.

He has reported continued health and freedom from ascites since discharge but refused any further laboratory study.

COMMENT

In some instances as indicated by cases 1 and 2, large amounts of ascitic fluid have been injected intravenously and the protein apparently has been retained in the blood stream. Following the injections there has been an increase in the serum protein level. As the serum protein level increased, a spontaneous diuresis was observed with complete reabsorption of the remaining ascites. Clinically, improvement in these cases was maintained for a considerable period after the completion of the series of injections.

The biggest difficulty has been the matter of reactions. They seem to be more frequent if the ascitic fluid is injected immediately after tapping. The paracentesis is done under sterile conditions and the fluid

is saved in transfusion bottles, which are kept in the ice box, where cells and bits of fibrin are allowed to settle out. Sterility is confirmed by cultures and the protein content is determined. After twenty-four to seventy-two hours the clear fluid is siphoned off and given intravenously. The infusion is made at room temperature. For the most part it has been given in amounts of 500 to 1,000 cc a day rather than as larger single injections. When these precautions are observed, reactions have been infrequent, though an occasional slight chill has been noted. When the ascitic fluid has been very dilute with less than 1 per cent of protein, the amount of protein lost has not been sufficient to warrant its reinjection. However, if the ascitic fluid contains more than 1 per cent of protein, this procedure has been used. A satisfactory response has not been obtained in all cases. The exact details for the handling of the ascitic fluid have not been completely established, but, in selected cases when the protein concentration of the fluid is high and the serum proteins are reduced, I believe that this method of conserving protein is of value in the management of ascites.

Not only is anemia present in cases of cirrhosis, but in the more severe cases this anemia is of the hyperchromic macrocytic type and the blood picture is not unlike that seen in pernicious anemia. This is due to the fact that the damaged liver is no longer able to store the antianemic fraction of the food. In these cases the blood count can be improved and the anemia controlled in part by the intramuscular use of large doses of liver extract just as in cases of pernicious anemia.

The patient with cirrhosis frequently shows a reduction in the prothrombin time of the blood which, if pronounced, will cause a tendency to hemorrhage. The prothrombin time of the blood of a patient with cirrhosis, therefore, should be watched and sufficient vitamin K administered to keep this at a normal level. In the more severe cases of cirrhosis this may not be possible because the severely damaged liver is unable to form prothrombin even though an adequate supply of vitamin K is present.

The most serious hemorrhages in cases of portal cirrhosis usually are due to ruptured esophageal varices. Many different methods have been tried to reduce the portal flow or obliterate the varices with varying degrees of success—splenectomy used by W. J. Mayo³⁵ and ligation of the coronary vein of the stomach alone as described by Walters³⁶ or combined with the ingestion of sodium morrhuate into the intra-abdominal vessels as used by Grace³⁷. Most recently Crafoord and Frenckner³⁸ and Moersch³⁹ have brilliantly demonstrated the possibility of the direct injection of the esophageal varices.

The most discussed surgical procedure in the treatment of cirrhosis has been the operation of omentopexy, which usually bears the names of Talva and Morrison. The consensus at present is that the results of opera-

tion as used in the past have been most unsatisfactory. At the same time a considerable number of cases have been reported in which there was freedom from ascites, with good health, five to twenty years afterward. This would suggest that the results depend in part on the type of cases selected for operation. I have seen a few cases in which apparently great benefit resulted from omentopexy. In some of these cases operation was performed before ascites developed. In others the continuance of ascites required paracentesis at frequent intervals. After six months to a year evidence of abdominal collaterals developed and ascites gradually cleared up. A considerable interval of time would seem to be necessary before the benefits of omentopexy can be expected to develop. As a last hope, after other methods of treatment have failed omentopexy would not seem to be indicated. Final conclusions as to its value cannot be drawn until a series of cases have been reported in which the operation was done early in the disease and enough time had elapsed for a collateral circulation, sufficient to relieve the portal hypertension, to develop. Even in such a series of cases the interpretation of results would be difficult, for the longer period of survival would also permit regenerative changes in the liver.

SUMMARY

Recent experimental studies have shown that cirrhosis of the liver can be produced in animals by dietary means. Fatty infiltration of the liver and vitamin deficiencies both play a role in the development of this cirrhosis.

Clinical evidence based in part on these experimental studies indicates the value of high protein, high vitamin diets in the treatment of patients with portal cirrhosis.

In selected cases, infusions of ascitic fluid seem to have some value in conserving blood protein and treating hypoproteinemia.

140 East Fifty-Fourth Street

ABSTRACT OF DISCUSSION

DR. SEYMOUR J. GRAY, Chicago: I was particularly interested in Dr. Greene's remarks on hypoproteinemia. Electrophoretic analyses of the serum proteins in various liver diseases indicate that two or more protein fractions are abnormal in every case. The most characteristic alteration of the serum proteins in liver disease is a large increase in gamma globulin and a decrease in serum albumin. These changes are seen most frequently and to the greatest degree in cirrhosis of the liver and next most frequently in the acute parenchymatous diseases. Although the serum globulin or albumin globulin ratio is not infrequently normal on chemical analysis in the acute parenchymatous diseases of the liver, the qualitative distribution of the alpha, beta and gamma globulins electrophoretically is invariably abnormal. Thus the qualitative distribution of the serum globulin fractions may be definitely abnormal electrophoretically in spite of a quantitatively normal serum globulin or albumin globulin ratio. Significant increases in beta globulin were observed in all types of liver disease but to a considerably less degree and frequency than the gamma globulin changes. Abnormalities of the serum proteins electrophoretically are less prominent in metastatic carcinoma of the liver than in any other form of liver disease. Jaundice alone does not produce any significant serum protein changes on electrophoretic analysis. The diseased liver according to our studies appears to produce the largest molecular weight protein fractions more readily than the smaller molecular weight fractions. This may be explained by Whipple's theory that protein is stored in the liver as complex protein aggregates which are broken down by the liver to supply the serum and tissue proteins as they are needed. Thus 'intermediate protein' is converted into gamma globulin by the

He has reported continued health and freedom from ascites since discharge but refused any further laboratory study.

COMMENT

In some instances as indicated by cases 1 and 2, large amounts of ascitic fluid have been injected intravenously and the protein apparently has been retained in the blood stream. Following the injections there has been an increase in the serum protein level. As the serum protein level increased, a spontaneous diuresis was observed with complete reabsorption of the remaining ascites. Clinically, improvement in these cases was maintained for a considerable period after the completion of the series of injections.

The biggest difficulty has been the matter of reactions. They seem to be more frequent if the ascitic fluid is injected immediately after tapping. The paracentesis is done under sterile conditions and the fluid

is saved in transfusion bottles, which are kept in the ice box, where cells and bits of fibrin are allowed to settle out. Sterility is confirmed by cultures and the protein content is determined. After twenty-four to seventy-two hours the clear fluid is siphoned off and given intravenously. The infusion is made at room temperature. For the most part it has been given in amounts of 500 to 1 000 cc a day rather than as larger single injections. When these precautions are observed, reactions have been infrequent, though an occasional slight chill has been noted. When the ascitic fluid has been very dilute with less than 1 per cent of protein, the amount of protein lost has not been sufficient to warrant its reinjection. However, if the ascitic fluid contains more than 1 per cent of protein, this procedure has been used. A satisfactory response has not been obtained in all cases. The exact details for the handling of the ascitic fluid have not been completely established, but, in selected cases when the protein concentration of the fluid is high and the serum proteins are reduced, I believe that this method of conserving protein is of value in the management of ascites.

Not only is anemia present in cases of cirrhosis, but in the more severe cases this anemia is of the hyperchromic macrocytic type and the blood picture is not unlike that seen in pernicious anemia. This is due to the fact that the damaged liver is no longer able to store the antianemic fraction of the food. In these cases the blood count can be improved and the anemia controlled in part by the intramuscular use of large doses of liver extract just as in cases of pernicious anemia.

The patient with cirrhosis frequently shows a reduction in the prothrombin time of the blood which, if pronounced, will cause a tendency to hemorrhage. The prothrombin time of the blood of a patient with cirrhosis, therefore, should be watched and sufficient vitamin K administered to keep this at a normal level. In the more severe cases of cirrhosis this may not be possible because the severely damaged liver is unable to form prothrombin even though an adequate supply of vitamin K is present.

The most serious hemorrhages in cases of portal cirrhosis usually are due to ruptured esophageal varices. Many different methods have been tried to reduce the portal flow or obliterate the varices with varying degrees of success—splenectomy used by W. J. Mayo³⁵ and ligation of the coronary vein of the stomach alone as described by Walters³⁶ or combined with the ingestion of sodium morrhuate into the intra-abdominal vessels as used by Grace³⁷. Most recently Crafoord and Frenckner³⁸ and Moersch³⁹ have brilliantly demonstrated the possibility of the direct injection of the esophageal varices.

The most discussed surgical procedure in the treatment of cirrhosis has been the operation of omentopexy, which usually bears the names of Talwa and Morrison. The consensus at present is that the results of opera-

tion as used in the past have been most unsatisfactory. At the same time a considerable number of cases have been reported in which there was freedom from ascites, with good health, five to twenty years afterward. This would suggest that the results depend in part on the type of cases selected for operation. I have seen a few cases in which apparently great benefit resulted from omentopexy. In some of these cases operation was performed before ascites developed. In others the continuance of ascites required paracentesis at frequent intervals. After six months to a year evidence of abdominal collaterals developed and ascites gradually cleared up. A considerable interval of time would seem to be necessary before the benefits of omentopexy can be expected to develop. As a last hope, after other methods of treatment have failed omentopexy would not seem to be indicated. Final conclusions as to its value cannot be drawn until a series of cases have been reported in which the operation was done early in the disease and enough time had elapsed for a collateral circulation, sufficient to relieve the portal hypertension, to develop. Even in such a series of cases the interpretation of results would be difficult, for the longer period of survival would also permit regenerative changes in the liver.

SUMMARY

Recent experimental studies have shown that cirrhosis of the liver can be produced in animals by dietary means. Fatty infiltration of the liver and vitamin deficiencies both play a role in the development of this cirrhosis.

Chemical evidence based in part on these experimental studies indicates the value of high protein, high vitamin diets in the treatment of patients with portal cirrhosis.

In selected cases, infusions of ascitic fluid seem to have some value in conserving blood protein and treating hypoproteinemia.

140 East Fifty-Fourth Street

ABSTRACT OF DISCUSSION

DR. SEYMOUR J. GRAY, Chicago: I was particularly interested in Dr. Greene's remarks on hypoproteinemia. Electrophoretic analyses of the serum proteins in various liver diseases indicate that two or more protein fractions are abnormal in every case. The most characteristic alteration of the serum proteins in liver disease is a large increase in gamma globulin and a decrease in serum albumin. These changes are seen most frequently and to the greatest degree in cirrhosis of the liver and next most frequently in the acute parenchymatous diseases. Although the serum globulin or albumin globulin ratio is not infrequently normal on chemical analysis in the acute parenchymatous diseases of the liver, the qualitative distribution of the alpha, beta and gamma globulins electrophoretically is invariably abnormal. Thus the qualitative distribution of the serum globulin fractions may be definitely abnormal electrophoretically in spite of a quantitatively normal serum globulin or albumin globulin ratio. Significant increases in beta globulin were observed in all types of liver disease but to a considerably less degree and frequency than the gamma globulin changes. Abnormalities of the serum proteins electrophoretically are less prominent in metastatic carcinoma of the liver than in any other form of liver disease. Jaundice alone does not produce any significant serum protein changes on electrophoretic analysis. The diseased liver, according to our studies, appears to produce the largest molecular weight protein fractions more readily than the smaller molecular weight fractions. This may be explained by Whipple's theory that protein is stored in the liver as complex protein aggregates which are broken down by the liver to supply the serum and tissue proteins as they are needed. This "intermediate protein" is converted into gamma globulin by the

diseased liver more readily than into the smaller protein fractions as alpha globulin and albumin. Finally, our studies indicate that the serum protein changes in liver disease result primarily from the inability of the liver to produce normal serum proteins rather than from external loss in the ascitic fluid.

DR W. B. YEGGE, Denver: I heard several members of the audience say that Dr. Greene had not mentioned what he thought about bile salts in the treatment of cirrhosis. You must remember Dr. Greene's paper had to do with portal cirrhosis, and portal cirrhosis and biliary cirrhosis are two separate things. Bile salts are more often used in biliary cirrhosis. There are different types of bile salts, and some of them are used for biliary drainage and others for liver cell stimulation. This brings up one thing of which I hope the Council on Pharmacy and Chemistry will take note, and that is that there should be some way in which these drugs could be labeled so we would know with what we are dealing. I should like to have a label put on each drug showing exactly what it contains so that the practicing physician would know what he is using. It is annoying to be educated by detail men who know only what some one has told them about a particular drug.

DR WALLACE M. YATER, Washington, D. C.: I should like to bring up the point of the great difficulty of early diagnosis in most cases of cirrhosis. If we could diagnose our cases earlier, diet, abstinence from alcohol and other toxic agents would be all that would be necessary. Lately choline has been used more or less experimentally in cases of cirrhosis of the liver. During the last year I have used it perhaps in 15 cases. Some of these patients went along and died promptly, not because of the choline but in spite of it. Other patients have remained about the same and some have improved. However, these patients have received a diet such as Dr. Greene has prescribed and the necessary vitamins and iron when iron deficiency was apparent, so that it seems hardly likely to me from these cases and from reading the reports of a few others in which choline has been used that we can expect very much from this form of treatment. The use of amino acids in bringing up the plasma proteins has to me been very discouraging. I have used it both parenterally and by mouth in pretty large doses and do not believe that it has caused any elevation of the plasma proteins in the cases in which I have used it. The remarkable effects that I have noticed in cases of severe plasma protein deficiencies associated with ascites have been the result of the infusion of plasma itself. This, of course, is an expensive form of treatment, but if one gives from 250 to 500 cc every two or three days until 3,000 cc has been given the most remarkable result appears in many cases. Plasma proteins become elevated and a great diuresis results. The ascites may not reform for quite a long time before more plasma is necessary. To date, however, it appears to me that the most important advance in treatment is the dietetic one associated with the use of vitamins and iron when necessary. However, there still remains the problem of getting these patients to eat. Many of them, of course, do not have a particularly good appetite. That brings up the question of preparing food concentrates. I have been employing various soybean preparations and, strangely enough, although I don't like them myself many patients do, and we have been able to give them a much higher carbohydrate-protein diet with the use of the soybean preparations than in any other way.

DR CARL H. GREENE, New York: The discussion has emphasized one point that I did not have time to make—the change in the qualitative nature of the proteins. I think the change in the character of the proteins is the factor responsible for the clinical value of such qualitative tests as the Takata-Ara and more recently the Hanger flocculation test. The latter is of especial diagnostic value in early diagnosis. I did not take up the question of bile salts because they are of no therapeutic importance in portal cirrhosis and I doubt if they have very much in biliary cirrhosis. My own experience has convinced me that the damaged liver does not respond well to bile salts. It cannot pick them up and it does not secrete them too well. I don't think they are safe in whipping up a damaged liver. Dr. Yater mentioned the use of amino acids intravenously. That is a valuable procedure in a selected series of cases, but

when one can get the patient to take it by mouth I think it is preferable to give the extra protein by mouth rather than intravenously. I am glad Dr. Yater's experience with plasma has been similar to my own. He brought out the one determining factor in my work and that was the question of expense. For many of these patients plasma is so expensive that it is prohibitive. Under these conditions if one is fortunate the patient's own ascitic fluid can be used as a much cheaper substitute.

THE GASTROINTESTINAL TRACT AND THE LIVER

FRANK C. MANN, MD

ROCHESTER, MINN.

The anatomic, physiologic and pathologic relations between the gastrointestinal tract and the liver are discussed frequently, but many problems arising from these relations remain unexplored. It is my purpose to present some of these problems with the view of emphasizing their probable importance rather than supplying an answer to them.

The liver can rightly be considered as one of the organs of digestion because it produces a secretion which is passed into the intestine and which is important in the maintenance of normal digestion. However, the liver is of much more significance in relation to the digestive tract than being merely one of the organs producing a digestive secretion. It is in addition the organ through which most of the products of digestion pass before reaching other tissues of the body. In this capacity it can be considered as a filter of the blood that has passed through the organs that have to do with the digestion and absorption of a large percentage of the food substances that enter the body.

The pathway between the gastrointestinal tract and the liver is the portal circulation. All the blood from the gastrointestinal tract, spleen and pancreas, except the small amount that drains through collateral channels, passes through the liver. The portal circulation therefore is of considerable importance, not only in a consideration of coordination of functions of the gastrointestinal tract and the liver, but also in relation to the development of pathologic conditions in the two organs.

SPECIFIC CHARACTERISTICS OF THE PORTAL SYSTEM

The portal system has several characteristics some of which are particularly pertinent to hepatic activity. The portal vein drains one of the most vascular regions in the body. The amount of blood that reaches the liver through the venous component of the hepatic circulation may be relatively very large. Since the blood in the portal vein must pass through the capillaries and sinusoids of the liver before reaching the systemic venous system the pressure in the portal vein is normally higher than it otherwise would be. The vasomotor control of the blood flowing through the portal vein is located in the organs which are drained into the portal system. Thus the major source of blood supply to the liver is not controlled within the organ, although the total outflow from the liver may be temporarily restricted by a mechanism located in the small hepatic veins.¹

THE LIVER AS A FILTER OF THE BLOOD FROM
THE GASTROINTESTINAL TRACT

Beginning in fetal life, many of the substances that reach the other tissues of the body must first pass through the liver. Evidence indicating the importance of this anatomic fact in relation to hepatic activity and the development of pathologic conditions in the organ is much more meager than the speculations regarding it. Most of the theories in this regard have dealt with the detoxifying functions of the organ. Data proving that the liver has an enhanced physiologic activity with regard to specific substances owing to their higher content in the portal blood as compared with their content in the systemic blood are few. It has been shown that some substances, as strychnine,² are readily destroyed in the liver, that transformation of dextrose into glycogen appears to be greater when the content of the former in the portal blood is high,³ that relatively large amounts of colloidal substances are removed from the portal blood by the stellate cells in a single passage through the organ⁴ and that dyes can be injected into the portal vein in amounts which will stain the liver but not cause a discernible coloration in other tissues of the body.⁵ Such evidence would indicate that the liver does serve as a filter for the portal blood but the full import of hepatic activity in this respect requires further investigation. The results of investigations on this problem may be of significance in the evaluation of those liver function tests in which the test substance is administered orally.

AMOUNT OF PORTAL BLOOD FLOW

The liver possesses two sources of blood supply, arterial and venous. Questions concerning the circulation of the liver have dealt, not only with the total amount of blood flow to the organ, but also with the relative amount from each source and whether or not the blood from the separate sources served different functions. Answers to these questions have been obtained in part. Measurements of the amount of blood flowing to and from the liver indicate that the total amount of blood flow to the organ is relatively large and varies within wide limits, that the relative amount of the total flow reaching the organ through either the arterial or venous component likewise varies greatly although the flow through the portal vein is always much greater than through the hepatic artery, that often there is a reciprocal response between the flow in the portal vein and hepatic artery,⁶ that under certain conditions the flow can be increased or decreased simultaneously in each and under other conditions increased separately in each,⁷ that in general, substances that stimulate the liver, as bile salts, increase the blood flow mainly in the artery.⁸

CHANGES IN PORTAL BLOOD FLOW

Under certain physiologic conditions the flow of blood in the portal vein can be greatly increased. The best examples of physiologic states that are accompanied by

increase in portal blood flow are digestion and exercise. The ingestion of a meal is followed by an increase in flow of blood throughout the body and the blood flow in the portal vein is also increased greatly.⁹ Likewise there is an increased flow of blood through the portal vein as well as to the muscles in muscular exercise.¹⁰ It is presumed that increased hepatic activity is associated with the greater flow of blood. It is assumed that both digestion and exercise produce an increase of functional stress on the liver. The giving of functional tests under the stress of digestion or exercise might supply data that would be of physiologic as well as clinical value.

CHARACTER OF FLOW OF BLOOD IN THE
PORTAL VEIN

The character of flow of blood in the portal vein appears to be important. Considerable evidence has accumulated which indicates that the flow in the portal vein is streamlined. The results of experiments in which india ink, dyes, emulsions of oil and other substances have been injected into various tributaries of the portal vein and their site of localization in the liver has been determined, as well as direct observation of the flow in the vein by transillumination, demonstrate that the blood in the portal vein originating from various sources is not completely mixed. There is a selective distribution of portal blood in the liver. The blood from the upper part of the gastrointestinal tract and spleen goes mainly to the left portion of the organ, while the rest of the portal blood has a greater distribution and goes to the right side.¹¹

The importance of this selective distribution of portal blood from different sources in the liver is not known and the problems involved are mainly unexplored, but some theoretical considerations may indicate its possible significance. Food products that are absorbed from the upper loops of the intestine go mainly to the left portion of the liver while the absorption products from the lower portion of the intestine pass in a larger amount through the right side. If food substances are given in form and amount so that absorption occurs in a localized length of intestine, only a relatively small portion of the liver will receive the portal blood that contains the high concentration of absorbed substances. It would appear that, if the whole liver is to function as a filter for the products of digestion, the ingested meal should be of such an amount and contain such types of food as would insure absorption from the entire length of intestine. It is conceivable that reactions to certain specific food substances may be due to the fact that such substances are absorbed so quickly from the upper portion of the intestine that the localized region of the liver through which they pass may be unable to prevent their reaching the systemic circulation in a sufficient concentration to cause an effect. The decreased toxicity of certain substances when given with food may be in part due to the specific distribution of portal blood in the liver.

While the previous statements have been concerned with the absorption of food, they would appear to be

pertinent also to the absorption of those substances used in hepatic function tests that are administered orally. It is worthy of question whether such substances, administered in a fasting state, pass through more than a limited amount of hepatic tissue before reaching the general circulation. The difference, as far as circulating through the liver is concerned, between substances administered orally and intravenously may not be great. Comparative tests, in which the orally administered test substance would be given in the fasting state and with an inert meal which would insure absorption from the entire length of small intestine, might give different results.

Theories concerning the action of a substance as predicated on its effect in passing through the liver before reaching the systemic circulation should take the specific distribution of blood from the different organs draining into the portal system into consideration. One example can be given. Higgins and I¹² injected gentian violet into the vein which drains the major portion of the pancreas in the rat and found that the left lobes of liver were stained by the dye while the right lobes were unstained. Evidently the right half of the liver receives insulin in a concentration no greater than the other tissues of the body.

The production of a localized lesion in the liver by a toxic substance gaining entrance to the portal circulation through the gastrointestinal tract has been difficult but can be easily accomplished with the spleen as the port of entry. Bollman and I¹³ injected carbon tetrachloride repeatedly into the spleen and produced an atrophic form of cirrhosis in the left lobes of the liver which was associated with a compensatory hypertrophy of the other lobes of the organ.

EFFECT ON THE LIVER OF LOSS OF PORTAL CIRCULATION

The importance of the portal circulation to the liver is emphasized by the changes produced in the organ by the loss of the blood reaching it through the venous component of its circulation. When the blood in the portal vein is diverted from its normal course directly into the vena cava, the liver atrophies to approximately half its normal size or less and certain definite changes in its gross and microscopic appearance occur which are almost characteristic.¹⁴ The effects on the liver produced by loss of portal blood supply are due not only to the great decrease in total blood supply but also to the fact that certain localized regions of the hepatic lobule receive little or no blood from the hepatic artery.¹⁵ The capacity of the liver for restoration is almost completely abolished with the loss of blood from the venous component.¹⁶ On the other hand, regeneration of hepatic tissue after injury appears to begin in the islands of seemingly normal hepatic cells that are supplied mainly or entirely by arterial blood while the cells in the regions supplied only by portal blood may be too badly injured to regenerate hepatic tissues.¹⁷ Thus the intrahepatic portal pathways are gradually obliterated because the regions of hepatic tissue which

they supply are not regenerated. This process not only decreases the amount of regeneration but also diverts portal blood into collateral channels. Since the functions of the portal blood and arterial blood to the liver are somewhat different, comparable tests of liver function in the condition of cirrhosis in which the test substance is administered orally and intravenously might furnish different results.

EFFECT OF DISTENTION OF INTESTINE ON PORTAL BLOOD FLOW

Alterations in the flow of blood in the portal vein depend on changes in the amount of blood that passes through the organs that drain into the portal system. Many conditions may affect the blood flow from one or more of these organs. One illustration will be given. Herrick and I¹⁸ studied the effect of acute distention of the intestine with different pressures on portal blood flow and portal pressure. Our purpose in making the investigation was to determine if there was a basis for the possibility that distention of the intestine might affect hepatic activity by producing alterations in the portal circulation. Our results will be given briefly without reference to the controversial phases of the subject. We found that the effect of distention of the intestine on the flow of blood in the portal vein was variable. Usually the flow decreased progressively with increases in intraintestinal pressures but occasionally the portal flow would increase slightly or remain unchanged. Pressure in the portal vein always increased and when the intestine was greatly distended almost equaled the intraintestinal pressure. Evidently distention of the intestine may produce alteration in the portal circulation to such an extent that hepatic activity could be affected.

EFFECT OF OBSTRUCTION OF BILIARY OUTFLOW ON INTESTINAL ACTIVITY

Alteration in the liver either physiologic or pathologic may affect the normal function of the intestine. This statement is especially pertinent to the condition of obstruction of the common bile duct. Obstruction of the biliary outflow and the retention of the constituents of the bile in the liver and other tissues throughout the body may affect the functions of the intestinal tract owing to (1) lack of bile in the intestine or (2) effect of retained constituents of bile on (a) intestinal secretion and (b) motor mechanism.

Observations on intestinal activity in the presence of jaundice are meager. Canonico and I¹⁹ made an experimental study of intestinal activity before and after ligation of the common bile duct using methods which permitted observation and recording of activity of loops of jejunum and ileum under nearly normal conditions. We found that biliary obstruction was followed by a definite decrease of activity in the loops of intestine under observation during the first two weeks after operation. Intestinal activity subsequently increased but never equaled the normal amount in the jaundiced animal. A comparison of the activity of the intestine before and after obstruction of the common bile duct showed that, although the decrease occurred in both the fasting and digesting states, it was more noticeable in the latter. Some suggestive evidence was obtained indicating that the biliary constituents retained in the blood, particularly the bile salts, may be of importance in causing the decreased intestinal activity noted.

LIVER FUNCTION TESTS

A GENERAL EVALUATION OF LIVER FUNCTION TESTS, AND AN APPRAISAL OF THE COMPARATIVE SENSITIVITY AND RELIABILITY OF THE NEWER TESTS, WITH PARTICULAR EMPHASIS ON THE CEPHALIN-CHOLESTEROL FLOCCULATION TEST, THE INTRAVENOUS HIPPURIC ACID TEST AND AN IMPROVED BROMSULPHALEIN TEST WITH A NEW NORMAL STANDARD

JOHN G. MATEER, MD

JAMES I. BALTZ, MD

DONALD F. MARION, MD

AND

JAMES M. MACMILLAN, MD

DETROIT

This discussion deals, first, with a general evaluation of liver function tests and with the importance of adequate and carefully conducted normal control studies. In the second place the comparative sensitivity and reliability of the newer tests, in relation to each other and to the older tests, as evaluated in a recent publication of ours,¹ are reviewed and summarized. Finally, an improved bromsulphalein method has been developed using 5 mg of the dye per kilogram and employing a new time interval as the normal standard for complete disappearance of the dye from the blood stream.

GENERAL EVALUATION OF LIVER FUNCTION TESTS

Liver function tests offer valuable aid in the evaluation of hepatic cell function. However, these tests should be regarded only as an aid to clinical and other laboratory findings in the diagnosis of the exact pathologic conditions. Liver function tests indicate the existing functional state of the hepatic cells but they do not reveal the cause of the impaired function. They do not indicate whether impaired function is due to a toxin circulating in the blood stream, an acute or chronic infection, faulty diet, compression of liver cells by scar tissue or metastatic carcinoma within the liver or to any one of several other causes. Nor do these tests indicate whether the underlying cause is an acute condition or a more serious, chronic, progressive type of hepatic disease. However, if one knows from clinical and other laboratory or x-ray studies the general nature of the pathologic condition, then the results of the liver function tests are of unusual value. They assume real importance in preoperative and postoperative treatment and in evaluating the degree of impairment, the effectiveness of medical treatment, and the prognosis.

From the practical point of view of the clinician, a basis for liver function tests is being developed on which they do measure, either directly or indirectly, the capacity of the liver to function adequately under various circumstances. To achieve this objective the most urgent need is for normal control studies to demonstrate more accurately the extent of normal variations and to denote more exactly the line of demarcation between normal and abnormal hepatic function. That

the newer liver function tests do measure something of practical importance is evidenced by the close parallelism between changes in the results of these tests and changes in the clinical picture. It has been demonstrated that these tests have both diagnostic and prognostic value.

Probably the most convincing, specific evidence that liver function tests do measure the impairment of liver function is found in a study of "catarrhal jaundice" or acute toxic degenerative hepatitis. In this condition in which the essential pathologic change consists in a destruction of many liver cells, followed by a gradual regeneration of normal liver cells, the liver function tests show a maximum deviation from normal relatively early in the course of the disease. As clinical evidence of hepatic repair develops, there is a continued and close parallelism in the improvement of the hepatic function tests.

In employing different liver function tests in identical cases one is impressed by the fact that there is no constant correlation of the results obtained with different tests. For example in 1 case tests A and B may both show impairment of liver function, in a second case test A may show impairment and test B no evidence of it and in a third case only test B may show impairment. This common observation can best be explained. Mann² has emphasized, by the hypothesis that the various functions of the liver are not injured equally under different conditions. There is a dissociation of impairment of different liver functions and a corresponding dissociation of the results of liver function tests.

Therefore, the wisdom of conducting several different types of hepatic function tests is obvious, if one expects to demonstrate evidence of impaired liver function in the greatest percentage of patients with liver damage.

LITERATURE AND HEPATIC FUNCTION
TEST METHODS

In a recent and much more comprehensive work¹ dealing with this same general subject, we reported the results of a comparative statistical study, conducted to determine the sensitivity and reliability of Hanger's cephalin-cholesterol flocculation test,³ Quick's intravenous hippuric acid test,⁴ a modification of Macdonald's 2 mg per kilogram serial bromsulphalein method⁵ and Gray's colloidal gold test⁶ in relation to one another and to the two older tests, viz the oral hippuric acid test⁷ and the original Rosenthal bromsulphalein method.⁸ The exact method used in the conduct of each test was outlined. The previous literature was reviewed in some detail.¹

Normal control studies were conducted on 40 normal young adults¹ varying between 25 and 35 years of age. Normal standards for each test were determined which would afford the maximum sensitivity compatible with reliability for each test.

From the Gastro Intestinal Division of the Medical Department Henry Ford Hospital.

Read before the joint meeting of the Section on Pathology and Physiology and the Section on Gastroenterology and Proctology at the Ninety Third Annual Session of the American Medical Association Atlantic City, N. J. June 12 1942.

1. Mateer, John G., Baltz, James I., Marion, Donald F., Hollands, Robert A. and Yagle, Elizabeth M. A Comparative Evaluation of the Newer Liver Function Tests. *Am J Digest Dis* 9: 13-29 (Jan) 1942.

In the conduct of the cephalin-cholesterol flocculation test on normal individuals it was learned that the test is reliable only if (1) unripened cephalin is used, as advised in Hanger's original publication,³ and (2) if the 1 plus tests are regarded as within normal limits and positive diagnostic importance is attached only to 2 plus 3 plus and 4 plus tests. (Ripened cephalin studies on normal controls yielded numerous false positive 2 plus and 3 plus results whereas unripened cephalin yielded only 12.5 per cent of false positive results and only 1 plus results with the normal controls.)

Normal control studies with Quick's intravenous hippuric acid method completely corroborated Quick's statement that any urinary output of less than 0.70 Gm of benzoic acid as hippuric acid in the one hour urine specimen indicates some degree of impairment of hepatic function.

The normal control studies with a modified serial 2 mg per kilogram bromsulphalein method (obtaining blood specimens every five minutes for thirty minutes after injection of the dye) revealed the fact that twenty minutes is the normal time for complete disappearance of the dye from the blood stream when the aforementioned dose is used and not thirty minutes as previously assumed. Therefore if one wishes to withdraw only a single blood specimen after injecting a 2 mg per kilogram dose of the dye instead of using the serial method one should withdraw the one blood specimen in exactly twenty minutes rather than in thirty minutes.

The results of the normal control studies with the colloidal gold test will not be referred to here since this test was found not to be adapted to routine laboratory use.

COMPARATIVE SENSITIVITY AND RELIABILITY OF THE NEWER LIVER FUNCTION TESTS

In the comparative study of the sensitivity of the four newer hepatic function tests referred to in relation to the two older tests viz the oral hippuric acid test and the Rosenthal bromsulphalein method (2 mg dose of the dye administered and a single blood specimen withdrawn thirty minutes later), the following results were obtained in a direct comparison of each test with every other test when conducted on an identical group of subjects.¹

The intravenous hippuric acid test yielded 85 per cent more positive tests than the oral hippuric acid test. This much greater sensitivity of the intravenous test is due to reasons previously specified.¹ The serial bromsulphalein method using the 2 mg per kilogram dose of the dye and twenty minutes as the normal clearance time for the dye yielded 100 per cent more positive tests than the thirty minute Rosenthal bromsulphalein method. The cephalin test yielded exactly the same number of positive tests as the intravenous hippuric acid test but 33 per cent more positive tests than the aforementioned serial bromsulphalein test.

A study of the relative sensitivity of these various tests in various pathologic groups of cases indicated that all four of the newer tests (including the colloidal gold test which is not satisfactory for other reasons) are appreciably more sensitive than the two older tests. Of special interest was the observation that in a group of 67 patients with gallstones studied before operation 53 per cent yielded a positive intravenous hippuric acid test, 50 per cent a positive cephalin test and 42 per cent yielded a positive serial twenty minute 2 mg, brom-

sulphalein test whereas only 15 per cent yielded a positive Rosenthal bromsulphalein test. This type of information is of great practical value in selecting cases of cholelithiasis needing special preoperative preparation.

The oral hippuric acid test, although much less sensitive than the three newer tests has one important advantage in a particular group of cases first, because it is less sensitive and a greater degree of liver impairment is necessary to yield a positive test and second because the extensive use of this test over some period of time has led to its well established evaluation. This test has a proved value in determining the operability of patients with known liver damage. Snell⁹ and White¹⁰ and we agree that if there is less than 50 per cent of the normal 3 Gm of hippuric acid excreted in the four hour urine collection viz less than 1.5 Gm this finding indicates that such a patient presents a very poor operative risk.

ADVANTAGES AND LIMITATIONS OF EACH TEST

The various advantages and limitations of each of the four newer tests and the two older tests have been outlined.¹ These deductions will not be repeated here.

AN IMPROVED BROMSULPHALEIN TEST

In the recent literature advocating the 3 mg per kilogram dose for the bromsulphalein test one finds a wide variation in the normal standard adopted by different workers. This situation is apparently due to taking inadequate precautions in establishing the exact range of normal variations. To avoid this pitfall two precautions would seem necessary. First in the study of normal individuals to establish the correct normal standard, it seems absolutely essential to conduct a serial type of examination after injection of the dye withdrawing a blood specimen for dye estimation every five minutes until after the dye has completely disappeared from the blood. Only in this way can the normal disappearance time be accurately determined and variations in the normal disappearance time of the dye correctly defined. In the second place it is obviously important to study an adequate number of normal individuals if the resulting normal standard is to represent the full range of normal variations. Reported studies of 8, 10 or 12 normal individuals represent an inadequate number of controls.

A New and Improved Normal Standard for the 5 Mg per Kilogram Bromsulphalein Test—In table 1 are presented the results of a study of thirty normal control individuals studied by the serial 5 mg per kilogram bromsulphalein method. In this group of healthy persons ranging from 25 to 35 years with no history of catarrhal jaundice or of any type of chronic gastrointestinal symptoms who had received 5 mg of bromsulphalein per kilogram the dye had completely disappeared from the blood stream in 73 per cent of these normal controls in thirty minutes, in 86 per cent in thirty-five minutes, in 96 per cent in forty minutes and in 100 per cent of these normal individuals in forty-five minutes. The forty-five minute period has been adopted therefore as the normal standard for complete disappearance of the dye after injection of 5 mg of bromsulphalein per kilogram.

¹¹ Footnote deleted on proof.

It is important to have a normal standard which yields no false positive tests with healthy young adults. At the same time it is not necessary to allow a longer period than the one which just fails to give any false positive results in the entire normal control group. In offering this new recommendation, that the result of this test be interpreted as normal or abnormal, depending on whether the dye has or has not completely disappeared from the blood in the forty-five minute specimen, the reliability of this time interval is enhanced when one realizes that the dye had completely disappeared from the blood in 86 per cent of the normal group in thirty-five minutes, and that the additional ten minutes is allowed to insure the diagnosis of normal

of dye retention as the upper limit of normal are open to one important criticism. For example one person may exhibit 10 per cent retention of the dye in thirty minutes and the dye may have completely disappeared from the blood in forty-five minutes. Another person may exhibit the same 10 per cent retention of dye in thirty minutes, but 4 or 5 per cent may still be present in forty-five minutes. This prolonged delay in the disappearance of the last small percentage of dye from the blood is quite characteristic of impaired liver function and will be noted in numerous cases if the serial bromsulphalein method is used. This fact has not been appreciated generally, because the serial method has not been employed.

* With the 5 mg per kilogram dose of dye it is noted that the dye has disappeared from the blood in every normal person in forty-five minutes whereas the normal disappearance time for the 2 mg per kilogram dose was twenty minutes.

† All of these 30 normal persons also yielded a negative cephalin test according to the normal standard recently established.

liver function in the remaining small 14 per cent subgroup of normal persons. Sensitivity of any test is advantageous only as far as it is associated with reliability.

As already noted, in the rather scant recent literature dealing with the use of the 5 mg per kilogram dose of bromsulphalein one finds a wide variation in the standard that has been adopted as normal by different workers.

Several have advised obtaining a single blood specimen in thirty minutes and specifying 6, 8 or 10 per cent retention as the maximum retention for a normal test. For example, Israel and Reinhold¹² regarded any retention of more than 6 per cent in thirty minutes as abnormal, whereas Rosenberg and Soskin¹³ accepted a retention of dye varying from 0 to 10 per cent in thirty minutes as within normal limits. Any of these standards which attempt to fix a particular percentage

On the other hand, those workers who have used a normal standard based on the complete disappearance of dye from the blood have used either thirty minutes or sixty minutes as the normal disappearance time of the dye. This wide variation again in normal standards is due apparently as already noted either to (1) a failure to use the serial method in determining the normal standard, (2) to studying an insufficient number of normal controls or (3) to not using sufficient care in selecting the cases that are used for normal control studies.

Although reliable, the allowance of sixty minutes for the normal clearance time of a 5 mg per kilogram dose of the dye detracts from the legitimate sensitivity of the test, since the normal control studies by the serial method shown in table 1 indicate that this time standard is unnecessarily generous and would fail therefore, to detect an appreciable number of cases with slight but definite impairment of liver function. On the other hand, Helm and Machella¹⁴ have recently advocated

thirty minutes as the proper normal disappearance time for the 5 mg per kilogram dose of dye. Our normal control studies by the serial method indicate that thirty minutes is too short a time and would render the test too sensitive. This time interval would yield, therefore, false positive tests. In 27 per cent of our normal control subjects the dye had not cleared from the blood in thirty minutes, although it had disappeared at this time in the other 73 per cent. The probable explanation

as sensitive as either the cephalin test or the intravenous hippuric acid test and at the same time a test which is just as reliable.

Serial Specimen, Single Specimen or Two Specimen 5 Mg Bromsulphalein Method (forty-five minute dye disappearance time).—From the standpoint of economy of time and effort a single forty-five minute specimen is satisfactory, since this correct normal standard has been determined by the serial method. Such a

* 5 mg dye test and cephalin test were conducted in 44 of the 46 cases listed in this table. 5 mg dye test and 2 mg dye test were conducted in 32 of the 46 cases listed.

† ND indicates that the test so specified was not conducted in this particular case.

These cases of portal cirrhosis all presented some evidence of portal obstruction (e.g., ascites, superficial collateral circulation or other evidence).
The cases of enlarged liver all presented either an alcoholic history or evidence of chronic gall tract disease in addition to some degree of enlargement of liver.

why Helm and Machella found the blood free from dye in thirty minutes in all their normal controls was that they report studying only 12 normal persons.

In this study of an improved 5 mg per kilogram bromsulphalein method, all estimations of the amount of retained dye in the blood have been conducted with a specially prepared 5 mg colorimetric standard which measures any residual dye in terms of percentage of the amount of dye originally injected.

The forty-five minute interval advocated in this publication for normal disappearance of the dye from the blood with the 5 mg per kilogram dose constitutes a new standard, which, as will be noted, provides a test

single specimen affords the necessary information, provided it is taken exactly at the proper time. A compromise between the serial and single specimen method which would constitute the most desirable method from a comprehensive point of view, would consist in obtaining a forty-five minute and sixty minute blood specimen, with separate venipunctures. This would avoid the need for giving intravenous saline solution to keep the needle open, when using the serial method and obtaining a number of blood specimens. At the same time, obtaining a sixty minute specimen, in addition to the forty-five minute specimen, would supply supplementary information regarding the degree of impaired

liver function in those cases presenting evidence of impairment in the forty-five minute specimen. Thus the further rate of excretion of the dye can be demonstrated in this group of cases.

Results Obtained with Improved Bromsulphalein Test (forty-five minute normal standard 5 mg per kilogram dose).—In table 2 the results of the serial 5 mg per kilogram, forty-five minute bromsulphalein method are compared (1) in 44 cases with the results obtained with the cephalin test in this same group of cases, and (2) with the results of the serial, 2 mg per kilogram, twenty minute bromsulphalein method with the 32 patients studied by these two serial dye methods (In all, 46 patients were studied.)

Like the group of 307 cases previously studied,¹ this group of 46 cases also included not only cases in which clinically obvious liver disease was present but also a number of cases of cholelithiasis, in which the hepatic impairment, when present, is usually of lesser degree.

5 mg dose represents an appreciably more sensitive test than the 2 mg dose.

The Influence of Variable Normal Standards in Producing Extreme Variations in Sensitivity of 5 Mg Bromsulphalein Test—When using various "normal" standards for the disappearance of the dye, as shown in table 3, extreme variations are exhibited in the sensitivity of the 5 mg bromsulphalein method, as compared with the cephalin test. (The cephalin test was conducted with the constant, recently recommended, normal standard¹) For example, if thirty minutes is used as the normal standard for complete disappearance of dye from the blood, the 5 mg per kilogram bromsulphalein test yields 76 per cent more positive tests than the cephalin test, if thirty-five minutes is used as the normal standard, the dye test is positive in 52 per cent more cases than the cephalin test, whereas if forty-five minutes, the most sensitive reliable normal standard for the 5 mg dye test, is used the cephalin test and the

4 45 minutes = disappearance time (normal standard recommended)‡	11	10	10	13	Exactly equal sensitivity of BSP and cephalin tests
5 60 minutes = disappearance time					Cephalin test would be appreciably more sensitive here #
6 Not more than 0% of BSP remaining in blood in 30 minutes	9	9	12	14	16% more positive cephalin tests
7 Not more than 10% of BSP remaining in 30 min	7	3	14	21	133% more positive cephalin tests
8 Not more than 15% remaining in 30 minutes	5	1	16	22	200% more positive cephalin tests

* The statistics in this table are deduced from those in table 2. The use of the serial method has made possible the comparisons shown.

† If even a trace of dye remained at any of the various normal time standards referred to in this table the test was interpreted as positive for that standard.

‡ That forty-five minutes is the correct normal standard for complete disappearance of the dye from the blood is indicated by the normal control studies listed in table 1.

The reason for this statement is discussed in the last section of this paper.

It is important to include cases of only slight and moderate impairment, as well as more advanced cases, when attempting to demonstrate the sensitivity of any liver function test.

It is noted in table 3 that the 5 mg bromsulphalein test yielded exactly the same number of positive tests as the cephalin test and therefore exhibited the same degree of sensitivity, provided the recommended forty-five minute disappearance time for the dye is regarded as a normal standard. It is also recalled that the intravenous hippuric acid test possesses approximately the same degree of sensitivity as the cephalin test. Therefore these three tests possess about the same sensitivity.

In comparing the sensitivity of the 2 mg and 5 mg bromsulphalein methods, using twenty minutes as the normal disappearance time of the dye for the 2 mg method and forty-five minutes for the 5 mg method, and utilizing the 32 cases in table 2, in which both dye methods were conducted, the following results were obtained. It is noted that the 2 mg test was positive in a total of 8 cases and the 5 mg test in a total of 13 cases. The 5 mg test was therefore positive in 62 per cent more cases than the 2 mg test and the

5 mg per kilogram dye test yield exactly the same number of positive tests in the 44 cases (table 3). In other words, these two tests possess the same sensitivity provided both tests are conducted with a reliable technique which affords no false positive tests. If the serial dye test had been prolonged for sixty minutes, and sixty minutes had been regarded as the normal standard, it is obvious from tables 2 and 3 that the sensitivity of the 5 mg dye test would have been appreciably reduced and that this test then would be much less sensitive than the cephalin test. In 54 per cent of the cases in table 2 showing a positive 5 mg test with the forty-five minute standard, 4 per cent or less of the dye remained at forty-five minutes, and this small amount of dye would almost certainly have disappeared in sixty minutes in most cases, if the serial method had been continued to sixty minutes.

Another interesting fact apparent from table 3 is that if some particular percentage of dye remaining in the blood at thirty minutes is used as the normal standard (instead of its complete disappearance) it makes a tremendous difference in the sensitivity of the dye test whether one uses as a normal standard an upper limit of 6 per cent of retained dye, as advised by Israel and

Reinhold, or an upper limit of 10 per cent, apparently the most commonly employed normal standard at the present time. If 6 per cent is regarded as the upper normal limit of dye retention, the cephalin test yields only 16 per cent more positive tests than the dye test, but if 10 per cent is regarded as the upper normal limit the cephalin test yields 133 per cent more positive tests than the 5 mg bromsulphalein test. If 15 per cent of retained dye is regarded as the upper normal limit for thirty minutes (a standard which is also used) the contrast in sensitivity becomes even greater. With this 15 per cent upper normal limit of retained dye the cephalin test yields 250 per cent more positive tests than the 5 mg bromsulphalein test.

The pronounced variations in the sensitivity of the 5 mg dye test, occurring with the use of slightly different percentages of retained dye as the "normal" standard for the thirty minute specimen, constitute a second reason why it is undesirable to use any particular percentage of retained dye at thirty minutes as a normal standard. The first and still more important objection to using this type of a normal standard, in contrast to the complete disappearance of the dye at a later period, has been stated under the discussion of normal control studies.

POSTSCRIPT¹⁵

Since the paper was presented, certain additional observations and conclusions of considerable practical importance have been noted.

A. In further studies with different cephalin antigens an appreciable variation in their sensitivity has been noted. It has been observed that the sensitivity of freshly made unripened cephalin, if kept in a stoppered flask in the ice box, increases gradually on standing over a period of four or five months. For example, the cephalin-cholesterol flocculation test was conducted recently on the serums of 150 patients with clinical evidence suggesting liver impairment, parallel tests being run on the same serums with freshly prepared unripened cephalin and also with similarly prepared "unripened" cephalin which had remained in the ice box for about five months. The latter cephalin tended to yield more positive reactions, e. g. frequently a 3 plus reaction as opposed to a 1 plus reaction, or a 2 or 3 plus reaction as contrasted with a completely negative forty-eight hour reaction. In other words, the unripened cephalin did ripen somewhat on standing in the ice box.

When similar parallel tests were conducted on the serums of 20 normal young control subjects the freshly made cephalin yielded no positive tests, whereas with the cephalin which had stood in the ice box 2 of the 20 normal serums yielded a 1 plus test in the final forty-eight hour reading. None yielded a 2, 3 or 4 plus test.

In our initial observations with the cephalin-cholesterol flocculation test previously reported the cephalin used was cephalin which had not been ripened in sunlight but which had stood in the ice box about four months. The 40 normal serums tested with this cephalin yielded 12.5 per cent of 1 plus forty-eight hour results but no 2, 3 or 4 plus tests. In other words, the results were quite similar to those more recently obtained with cephalin which also had stood in the ice

box an essentially similar period of time. With this type of cephalin 1 plus forty-eight hour results are not interpreted as being definitely positive.

Recent reports from other workers agree with our present impression that freshly made unripened cephalin is not sensitive enough to yield positive tests in a number of cases in which clinical or other evidence of impairment of liver cell function exists. The cephalin which has ripened in an ice box for four or five months is preferable. On the other hand, cephalin which had stood in the sunlight in an unstoppered bottle for a few weeks yielded numerous 2 and 3 plus false positive tests.

Recently several lots of a commercial preparation of cephalin (in the form of cephalin-cholesterol antigen ready for use), ripened in the sun by a special method and provided by the Difco Company of Detroit, have been tested. These lots yielded uniformly satisfactory results. The latter results ran almost exactly parallel to those obtained with the aforementioned cephalin which had stood in the ice box for five months. This commercial preparation was quite sensitive but yielded negative results throughout when tested against the serums of the 20 normal young subjects referred to except for a single serum (5 per cent), which yielded a negative result in twenty-four hours and only a 1 plus result in forty-eight hours. If this commercial antigen is used, at least a 2 plus result in forty-eight hours should be required, therefore, to indicate definite impairment of liver cell function.

The Difco Company has noted that the explanation of false positive results obtained on normal serums with certain sun ripened cephalin preparations consists in the fact that such antigens have not been ripened for a sufficiently long period of time.

B. The only objection to the 5 mg per kilogram dose of bromsulphalein dye consists in the fact that some patients have a transient reaction to the injection of this larger dose of dye. Such a reaction develops in certain cases regardless of whether the injection of the dye is or is not followed by the injection of isotonic solution of sodium chloride and the employment of the serial method. The reaction may consist of transient headache, a feeling of faintness and in some cases a chill. These symptoms tend to occur from forty-five to sixty minutes after the injection of the dye. The headache may persist for several hours. No unfavorable or prolonged after-effect has been demonstrated. This type of reaction rarely occurs after employing the smaller dose of 2 mg per kilogram of bromsulphalein.

C. In cases in which it is desired to determine mainly the presence or absence of a slight degree of impaired liver function, two or three of the most sensitive tests should be employed, e. g. the cephalin test, the 5 mg per kilogram forty-five minute bromsulphalein test and the intravenous hippuric acid test.

In cases in which it is not only desired to determine the presence of impaired liver cell function but also to obtain from the tests as much information as possible about the degree of impairment, there is an important advantage in using several tests of varying sensitivity, e. g. the very sensitive cephalin test, the 2 mg per kilogram twenty minute bromsulphalein test of intermediate sensitivity and the less sensitive oral hippuric acid test.

THE SIGNIFICANCE OF MILD HYPERBILIRUBINEMIA IN GASTRO-INTESTINAL PATIENTS

T A JOHNSON, MD

AND

H L BOCKUS, MD

PHILADELPHIA

The routine use of serum bilirubin determinations on nonjaundiced patients discloses a group in which the serum bilirubin value is elevated beyond the usually accepted normal figure but in which there has been no evidence of preceding or subsequent jaundice. Such a group may be said to have latent jaundice.

The presence of an isolated elevated serum bilirubin value in a case in which the routine diagnostic survey discloses no other abnormality imposes certain diagnostic responsibilities on the clinician. Shall he ignore the hyperbilirubinemia? In terms of milligrams per hundred cubic centimeters of blood, at what level should one infer that a given value represents hyperbilirubinemia? Naturally the average patient, seeking relief from some real or fancied ailment, does not represent a normal individual, and a large group of similar patients, by virtue of the size of the group alone cannot be considered a cross section of normal individuals. Nevertheless we believed that an analysis of a large group of patients who had submitted to a diagnostic study might afford some explanation for the presence of mild nonicteric hyperbilirubinemia. We are familiar with the fact that many observers, using the Thannhauser and Anderson¹ modification of the van den Bergh reaction, report normal values up to 1.5 or 2.0 mg per hundred cubic centimeters of blood. Careful estimations of serum bilirubin by more accurate methods indicate that there is a large error inherent in the Thannhauser and Anderson method. The many reasons justifying this critical attitude toward the Thannhauser and Anderson method are well known and need not be reiterated here. Nevertheless some modification of the Thannhauser and Anderson method is in use in most institutions where the serum bilirubin is studied.

In an attempt to determine the basic pathologic condition behind a given case of hyperbilirubinemia, the clinician may approach the diagnostic problem by considering one of the following mechanisms:

1 Obvious obstructive jaundice of high degree due to calculus requires little comment. However, mild or latent icterus due to intermittent ball valve action of a calculus may require intensive study to verify the suspected causal factor. Cholecystography may supply the chief objective diagnostic criteria in this instance. In a small group of cases, wherein the cholecystogram is doubtful, biliary drainage may afford aid by the demonstration of calcium bilirubinate pigment and cholesterol crystals. In the older age group incipient malignant conditions of the biliary tract including lesions of the head of the pancreas and vaterian cancer must be ruled out. A progressive icterus usually but not invariably points toward a malignant process. Persistent occult blood in the stools may point

toward malignancy of the pancreas or papillae of Vater. Varying degrees of hepatic dysfunction may occur in association with obstructive jaundice. Elevation of the serum phosphatase has been reported in obstructive jaundice, particularly when hepatic metastasis is suspected. We have derived comparatively little diagnostic help from the serum phosphatase in early icterus. An elevated serum lipase in the absence of acute inflammatory pancreatic involvement, is almost pathognomonic of pancreatic malignancy.

2 Typical cases of hemolytic jaundice are rare. In most instances the critical data consist of a palpable spleen, varying degrees of anemia, reticulocytosis, spherocytosis and increased fragility of the red blood cells. Familial types of hemolytic anemia together with sickle cell anemia must be ruled out. One must not overlook the fact that occasionally many of the aforementioned diagnostic tests may be normal or present such a small variation from normality that the diagnosis may not be clear. Sternal marrow biopsy may prove of inestimable value in some instances. Certain stages of primary macrocytic anemia (primary pernicious anemia) may be present with hyperbilirubinemia.

3 Toxic hepatocellular mechanisms, including catarrhal jaundice, cholangitis and the various types of chronic infectious jaundice will need to be considered. Frequently the diagnosis of cases in this group is inferential. In most instances however, the history, course of the disease and associated laboratory findings will indicate the type of involvement. The rapid onset of catarrhal jaundice in the younger age group, the rapidly changing and usually favorable clinical course, and a positive galactose tolerance test usually suffice to make the diagnosis. Occasionally an initial picture of catarrhal jaundice may merge into a mild latent icteric stage of varying duration. Acute yellow atrophy of the liver usually follows the exhibition of well known hepatotoxic drugs such as those containing the benzene ring, the arsphenamines, cinchophen and carbon tetrachloride. The recovery stage of acute yellow atrophy may be characterized by latent icterus. Subacute yellow atrophy in the absence of jaundice has been reported.

The term chronic cholangitis is a diagnostic pitfall and seems to be a convenient waste basket into which the busy clinician may cast cases of latent icterus which he cannot otherwise classify. Pathologically the distinction between mild catarrhal jaundice of the hepatocellular type and chronic cholangitis is difficult, and clinically the distinction may be impossible. The repeated recovery by bile drainage of plugs of mucus containing cellular debris and bacteria is said to be somewhat diagnostic of chronic cholangitis. Undoubtedly, chronic cholangitis is diagnosed largely on the basis of exclusion of other causes of latent icterus. Chronic infectious jaundice including that due to *Leptospira icterohemorrhagica* (spirochetal jaundice) offers many diagnostic difficulties. Spirochetal jaundice frequently is overlooked in this country. The various laboratory aids for identifying the causative agent afford the only reliable diagnostic criteria for spirochetal jaundice. Various other organisms occasionally may act as causative factors in chronic infectious jaundice.

4 Incipient spleen-liver disease, variously designated as splenic anemia or early Banti's disease comprises a relatively definite group of latent icteric cases in our experience. We are familiar with the paucity of etiologic factors in this group of cases but clinically certain features seem to predominate. We have studied

From the Gastro Intestinal Service, Graduate Hospital of the University of Pennsylvania.

Read before the joint meeting of the Section on Pathology and Physiology and the Section on Gastro-Enterology and Proctology at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1942.

a number of cases in which the initial complaint was a massive gastrointestinal hemorrhage and in which subsequent studies failed to reveal evidence of definite gastric or duodenal ulceration. In some of these, in addition to slight hyperbilirubinemia, blood studies revealed varying degrees of thrombocytopenia, leukopenia and prothrombin deficiency. There usually, but not invariably, is a palpable spleen and the liver may show slight enlargement. Liver function studies may reveal impaired function. One of our patients in this group had several exsanguinating hemorrhages at yearly intervals. Splenectomy coincided with cessation of the hemorrhages, although the thrombocytopenia and leukopenia persisted. Follow up of the nonsplenectomized cases has not been fruitful. Some continue with mild hemorrhages. We do not believe that any of them developed into a full blown cirrhotic stage of so called late Banti's disease.

5 There finally remain a small group of cases with persistent hyperbilirubinemia of undetermined origin

How large a percentage of cases is represented in this category will depend on the diagnostic elasticity of the clinician. For example, one who is fond of the diagnosis of chronic cholangitis may find that he has no cases of hyperbilirubinemia of undetermined origin. Our interest in this problem was stimulated by the fact that over a period of years we studied a group of patients with symptoms vaguely and in some cases strongly suggestive of duodenal ulcer in which mild hyperbilirubinemia persisted. We believed that estimations of serum bilirubin in all of our studied cases might prove of value. Because of this interest, the serum bilirubin was determined in a larger percentage of our office cases than was warranted by the suspicion of any abnormality referable to that test. In the past several years serum bilirubin determinations were performed on almost all our patients.

The present study comprises a group of private patients observed during the period from January 1930 to January 1942 in which serum bilirubin determinations were carried out.

The following technique² was used in the determination of the serum bilirubin.

Solution A. Dissolve 1 Gm of sulphuric acid in 15 cc of concentrated hydrochloric acid in water and dilute to 1 liter.

Solution B. Dissolve 0.5 Gm of sodium nitrite in water and dilute to 100 cc.

Diazo reagent. To a 10 cc graduated cylinder add 5 cc of solution A and 3 drops of solution B. Prepare fresh before each determination.

Saturated ammonium sulfate. In a bottle place 100 Gm of ammonium sulfate and 100 cc of water. Shake for some time to dissolve and use the supernatant fluid.

Standard cobalt solution. Weigh 2.161 Gm of anhydrous cobalt sulfate or 3.92 Gm of $\text{CoSO}_4 \cdot 7\text{H}_2\text{O}$, dissolve in water and dilute to 100 cc in a volumetric flask.

Standard series. To eight test tubes add respectively 10, 7.5, 5, 4, 3, 2, 1.5 and 1 cc of the standard cobalt sulfate solution. To the first seven add the correct amount of water to make 10 cc. Stopper and label respectively 2, 1.5, 1, 0.6, 0.4, 0.3 and 0.2 mg. The standard tubes are labeled to read directly in milligrams of bilirubin considering the 1-4 dilution in the method.

Pipet into a 15 cc centrifuge tube 1 cc of serum and 0.5 cc of diazo reagent. Mix. Stand three minutes. Add 2.5 cc of 95 per cent alcohol and 1 cc of saturated ammonium sulfate. Mix and centrifuge at a relatively high speed for five minutes. Remove the supernatant fluid and compare it with the standards in a test tube of the same size.

On the basis of this technique we had assumed that the majority of our normal serum bilirubin values occurred at or below 0.3 mg per hundred cubic centimeters of blood. However, there occurred a sufficient number of instances in which values in excess of 0.3 mg obtained that we believed it desirable to analyze all of our office cases in which serum bilirubin determinations were recorded during a twelve year period. Excluded were all isolated consultations in which no laboratory work was recorded or cases which were studied largely in the hospital. There remained a group of cases (3,782) which we regarded as having had a fairly complete study. Of the 3,782 cases, 1,835 (48.9 per cent) had one or more determinations of serum bilirubin. In cases with multiple determinations of serum bilirubin, the maximum value was used in this study. The serum bilirubin values in 1,835 cases were distributed as shown in table 1.

The 333 cases of hyperbilirubinemia (i.e. serum bilirubin in excess of 0.5 mg per hundred cubic centimeters of blood) were distributed as shown in table 2.

In the group of 333 cases of hyperbilirubinemia (i.e. a value above 0.5 mg per hundred cubic centimeters of blood) the maximum serum bilirubin values were distributed as outlined in table 3.

Of 3,782 cases comprising the total number reviewed, a diagnosis of duodenal ulcer was made in 641 instances. In 313 (48.8 per cent) of the 641 cases, one or more determinations of serum bilirubin were made. The serum bilirubin values in 313 cases of duodenal ulcer were distributed as shown in table 4.

It is evident that the general pattern of distribution of serum bilirubin values in the duodenal ulcer group was similar to that in the total group reviewed, an interesting observation in connection with those serum bilirubin values below 0.5 mg but of no practical importance in comparing the serum bilirubin values above 0.5 mg, since the total group comprised some jaundiced patients with liver and biliary tract disease in which one would anticipate an elevated serum bilirubin.

The diagnosis of duodenal ulcer was entertained only in those cases in which the history, physical examination, gastric analysis and roentgenographic demonstration of a niche supported such a diagnosis. The group labeled irritable duodenum comprised those cases

² Keller, A. G. Manual of the Biochemical Laboratories of the Graduate Hospital, University of Pennsylvania, 1934.

in which the clinical picture was not of sufficient clarity to warrant accepting as clearcut cases of peptic duodenal ulceration. While in some instances, undoubtedly the exclusion of certain cases from the duodenal ulcer group was based on capacious criteria, our general observations in this article might apply either to the duodenal ulcer or to the irritable duodenum group. The group labeled colon disease comprised all the cases in which any disorder referable to the colon was present, including malignant disease, polyposis, ulcerative colitis and irritable colon. The liver dysfunction group comprised all the cases of catarrhal jaundice, toxic hepatitis of all types, cholangitis and hepatic cirrhosis of nonobstructive origin. The obstructive jaundice group comprised those cases in which there was the common denominator of some factor or group of factors that gave rise to varying degrees of jaundice due to disease referable to obstruction to the outflow of bile from the biliary tract or associated structures. In the miscellaneous group we placed all the cases with diagnoses which were otherwise unclassified, such as malignant disease of the stomach, hypertension and hyperthyroidism.

Excluding 89 cases of obstructive jaundice from the 333 cases of hyperbilirubinemia, there remained 244

Cases studied over variable periods during which all of the serum bilirubin determinations fell within our defined range of hyperbilirubinemia.

Accordingly, the 244 cases of hyperbilirubinemia were grouped as shown in table 5.

TABLE 5—Groups of Cases of Hyperbilirubinemia

	A	B	C
Duodenal ulcer	23	4	4
Irritable duodenum	20	17	12
Colon disease	37	17	8
Miscellaneous	26	12	12
Liver dysfunction	22	26	9
	123	76	45

Thus there were 45 cases of persistent hyperbilirubinemia in which no clinical evidence of obstructive jaundice could be demonstrated.

The following analysis was made of the cases of persistent hyperbilirubinemia under each of the main diagnostic headings.

1 *Duodenal Ulcer*—Only 4 instances were noted in which persistent hyperbilirubinemia obtained in the duodenal ulcer group. The range of serum bilirubin values varied from 0.6 to 1.6 mg (1 case in which

TABLE 3—Maximum Serum Bilirubin Values in Cases of Hyperbilirubinemia

cases which were further analyzed in an attempt to segregate those cases in which persistent hyperbilirubinemia obtained. For convenience, the cases were subdivided into three categories.

A Cases in which only one serum bilirubin determination was recorded, obviously cases in which the persistence of hyperbilirubinemia was not considered.

B Cases in which hyperbilirubinemia was present at some time during the period of observation but in which subsequent determinations were within the nor-

TABLE 4—Serum Bilirubin Values in Cases of Duodenal Ulcer

Serum Bilirubin Mg per 100 Cc of Blood	No. of Cases	Per Cent
0.2	161	51.4

mal range. We likewise included in this group some cases in which hyperbilirubinemia was present during the whole course of a short period of observation, cases which certainly could not be regarded as showing persistent hyperbilirubinemia. Three cases observed for short periods in the liver dysfunction group in which death occurred likewise are included in this group.

five serum bilirubin determinations over a period of five years varied from 0.8 to 1.5 mg showed 0.3 mg on one occasion). In each case the cholecystogram showed a normally functioning gallbladder without evidence of calculi. Repeated bile drainage failed to demonstrate either calcium bilirubinate pigment or cholesterol crystals. In 2 cases the liver edge could be palpated on deep inspiration. A splenic enlargement was absent in all instances. Routine blood studies failed to reveal any hematologic abnormality. The urinary urobilinogen frequently was determined in each case and in no instance was the value any greater than a dilution of 1 to 30. In 1 case four bromsulphalein determinations (2 mg per kilogram dose) over a five year period varied respectively as follows: 20, 10, 0 and 7 per cent retention in thirty minutes. In no instance has there occurred any other clinical or laboratory evidence which might explain the persistent hyperbilirubinemia.

2 *Irritable Duodenum*—Twelve instances were noted in which persistent hyperbilirubinemia obtained in the irritable duodenum group. The range of serum bilirubin values varied from 0.6 to 2 mg. In 8 cases a cholecystogram was obtained which showed a normal gallbladder without stones in 5 cases. In 3 cases the cholecystogram showed a faint gallbladder shadow. In 10 cases one or more bile drainage examinations failed to demonstrate calcium bilirubinate pigment or cholesterol crystals. Many of the bile drainages showed evidence of moderate catarrh and exfoliation of the

biliary tract in the recovered material. In 1 case giardiasis was noted. In only 1 case was the liver edge palpable on deep inspiration. A splenic enlargement was absent in all instances. Routine blood studies failed to reveal any hematologic abnormality. The urinary urobilinogen was present in normal concentrations in each case on many determinations. Bromsulphalein retention tests were carried out in 8 cases. In 3 cases respectively 10, 6 and 5 per cent retention of bromsulphalein was noted, in 1 of which the bromsulphalein was zero at a subsequent examination. In 1 case three bromsulphalein determinations were reported 15, 10 and 2 per cent retention. Whether or not we are dealing with a case of early hepatic cirrhosis is not clear in the 1 case with a consistently positive bromsulphalein retention, although it seems unlikely because the other clinical and laboratory findings are

dye retention was noted. In 7 cases repeated determinations of the urinary urobilinogen were reported within normal concentrations.

4 *Miscellaneous*—There were 12 cases in the miscellaneous group in which persistent hyperbilirubinemia was present. Of these, 2 presented blood dyscrasias (primary macrocytic anemia and hemolytic icteroneumia) which could account for the hyperbilirubinemia. Two other cases present isolated findings (1 showed calcium bilirubinate pigment in the material recovered from the duodenum by biliary drainage and the other case showed a negative defect in one film of a cholecystographic series) not inconsistent with a diagnosis of cholelithiasis but in which the other clinical and laboratory studies failed to confirm the presence of gallstones. There remained only 8 cases in which consideration was given to unexplained hyperbilirubin-

within the normal range. Not 1 of our hyperbilirubinemia cases in either of the duodenal categories has shown any evidence either of definite or of progressive hepatic damage.

3 *Colon Disease*—There were 8 cases in which persistent hyperbilirubinemia obtained in this group with primary colonic disease. The range of serum bilirubin values varied from 0.6 to 1.5 mg. In 7 cases a cholecystogram was obtained which was normal in 4 cases, in 1 case the cholecystogram showed a faint shadow, in 1 case the gallbladder was sluggish and in 1 case there was a slight mottling in the gallbladder shadow. In the last case the collateral clinical and laboratory data did not support a diagnosis of cholelithiasis. Biliary drainage was done in 5 cases and, although at times the recovered material from the duodenum contained some exfoliative debris, no calcium bilirubinate pigment or cholesterol crystals were reported. In 2 instances the liver and splenic edges could be palpated on deep inspiration but there was no great increase in the size of either organ. In 4 cases the bromsulphalein dye retention test was performed, in 3 of which no retention was reported, in 1 case 8 per cent

emia. In 2 of the cases no cholecystograms were recorded, of the remaining 6 cases, 2 showed sluggish gallbladders and in none was there any evidence of cholelithiasis. Biliary drainage was attempted in 4 cases, 3 of which showed some flocculent debris suggesting catarrh, 1 showed giardiasis and in none were either calcium bilirubinate pigment or cholesterol crystals recovered in the duodenal material. The bromsulphalein retention was normal in the 3 cases tested. One case showed urobilinogenuria in the dilution of 1 to 30, the other cases were all reported 1 to 20 or less.

5 *Liver Dysfunction Group*—There were 9 cases in the liver dysfunction group with persistent hyperbilirubinemia, all of which might be segregated under the heading of chronic cholangitis. In these cases we were dealing with certain intangibles in which persistent hyperbilirubinemia was the only common finding. In table 6 the essential data are tabulated. Attention is directed to the length of the periods of observation, in one instance fifteen years. The serum bilirubin values in each case appear to range within definite limits without wide variations. The values for brom-

sulphalein retention do not indicate extensive liver damage. The urobilinogen figures are not indicative of any progressive hepatic disease. The bile drainages universally showed evidence of biliary catarrh and exfoliation, similar to those which B. B. Vincent Lyon³ attributes to cholangitis of varying degree. In no instance was the spleen palpable and in only 1 case was the lower margin of the liver easily felt. The cholecystograms were variable but in general indicated adequate gall-bladder function. In 1 case the roentgenologist was unwilling to exclude cholelithiasis, however, the other clinical and laboratory evidence failed to support a diagnosis of calculus disease.

COMMENT

A survey of the foregoing material suggests the following:

1 Hyperbilirubinemia of moderate degree is frequently encountered in gastrointestinal patients.

2 The most obvious cause of hyperbilirubinemia is obstructive jaundice.

3 In cases in which obstructive lesions of the biliary system can be excluded, one must search for other factors which might give rise to jaundice.

4 There exists a small group of cases with idiopathic persistent hyperbilirubinemia lasting, in some instances, over a period of years, in the absence of obvious etiologic factors.

5 In our series there were no instances of pronounced delayed hepatic changes associated with persistent hyperbilirubinemia.

Some of the limitations of the value and validity of the observations recorded in the presentation might be noted:

1 Of 3,788 cases studied, serum bilirubin determinations were made in 48.9 per cent. The clinical suspicion that some serum bilirubin abnormality might be present in only approximately one half of our cases immediately introduces a large variable. A similar series of 3,788 cases in each of which a serum bilirubin determination was made would offer more accurate data. Serum bilirubin determinations on a similarly large group of normal persons would offer still more evidence on the range of values in normal persons.

2 The number of cases in which repeated serum bilirubin determinations were made is too small to offer any valid data concerning the range of normal values in any given group of patients.

3 Careful studies by other investigators on the range of normal serum bilirubin values indicate variations due to certain technical difficulties with the test itself. The relation of concentrations of serum bilirubin to serum proteins introduces a large variable. Mindful of these limitations, we believed that a review of our experience with the test as performed in private practice might prove of some value. Apparently abnormal serum bilirubin values occur frequently in the routine study of office patients. The clinician must assume the responsibility either of ignoring such values or of attempting to determine their etiology.

CONCLUSIONS

1 Hyperbilirubinemia may be due to obstructive jaundice, hemolytic jaundice, toxic hepatocellular disease and incipient liver-spleen disease. In a small group of cases idiopathic hyperbilirubinemia must be considered.

2 A review was made of 1,835 cases in which one or more serum bilirubin determinations were recorded.

3 Serum bilirubin values in excess of 0.5 mg per hundred cubic centimeters of blood were termed hyperbilirubinemia.

4 The distribution of the serum bilirubin determinations indicated that 18.3 per cent of the serum bilirubin values were above 0.5 mg per hundred cubic centimeters.

5 The distribution of the hyperbilirubinemia values was determined in our cases of duodenal ulcer, irritable duodenum, colon disease, miscellaneous disease, liver dysfunction and obstructive jaundice.

6 Further consideration of the clinical and laboratory data in association with persistent hyperbilirubinemia indicates that in a small group of cases followed over a period of years mild hyperbilirubinemia obtains in the absence of hematologic or obvious progressive hepatic disease.

THE CLINICAL PREVENTION AND DIAGNOSIS OF LIVER DYSFUNCTION

SIDNEY A. PORTIS, M.D.

Associate Professor of Medicine, University of Illinois
College of Medicine
CHICAGO

Liver disease and liver dysfunction are becoming increasingly prevalent. It is now known that any chronically deficient diet may lead eventually to liver disease.

The American dietary is reported deficient in the vitamin B complex. One might assume that the recent enthusiasm for the intake of concentrated vitamin preparations might have counteracted this. However, two factors have nullified to a large extent the possible beneficial effect of increased vitamin intake. 1 Concentrated vitamin preparations are relatively expensive, and those who can afford to take them get an adequate amount in their diet, anyway. 2 A large proportion of commercial preparations do not contain the whole vitamin B complex—are apt to be rich in thiamine and nicotinic acid but poor in the other factors. There is some evidence to show that this disproportion can do harm as well as good. The desire for “slyphlike” figures has undoubtedly induced lowering of the carbohydrate intake. Man has enough carbohydrates or sugars in reserve to last only about one-half day. A certain amount of carbohydrate is essential in the diet if one is to avoid abnormal use of body fat. The hyperlipemia brought about by deficient carbohydrate intake leads to deposition of fat in the liver, producing fatty cirrhosis. Therefore, not only is the glycogen reserve of the liver depleted but the fatty replacement impairs normal liver function. Since an important function of the liver is detoxicating, toxic substances passing into it from the digestive tract may damage it further, owing to lowered local tissue resistance. These substances may even pass into the general circulation, where in turn they set up tissue changes which interfere with normal metabolism and may even lead to retrogressive changes. One may postulate that some of the noninfective types of arthritis may be related to this pathologic function.

From the Medical Department of Michael Reese Hospital and the Medical Department of the University of Illinois College of Medicine. Read before the joint meeting of the Section on Pathology and Physiology and the Section on Gastroenterology and Proctology at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1942.

³ Lyon, B. B. V. Nonsurgical Drainage of the Gall Tract. Philadelphia: Lea & Febiger, 1923.

The coexistence of gallbladder disease and hepatitis forms another interesting situation. Many physicians believe that cholecystitis and cholelithiasis produce liver damage which may reach an advanced degree. This is especially true in persons who have acute episodes of suppurative gallbladder disease repeated at intervals.

Fig. 1—Effect of cholecystectomy on the daily urinary sugar output by a patient with hepatic damage and glycosuria who had received insulin at the outset and intravenous dextrose without insulin later.

Therefore, unless there is a definite contraindication which may add to the morbidity and mortality associated with surgical intervention, it may be wise to remove a calculous gallbladder to prevent liver damage. Certainly, when there is little surgical risk, I can see no good reason for failure to remove a pathologic gallbladder. In addition, the subgastric acidity and achlorhydria that may develop without operation lead to a lowering of the bactericidal activity of the gastric juice. This may promote the development of flora in the upper part of the jejunum and duodenum which may be a factor in ascending infections to the liver and lead to additional liver damage. Therefore, more accurate evaluation of disease of the gallbladder may be an important factor in removing a source of continued liver damage and allow the normal reparative processes of this organ to go on unhampered.

The effect of various diets on liver damage has recently been investigated by Earle¹ and others. They found that feeding rats a diet containing 10 per cent cystine leads rapidly to portal necrosis and hemorrhage and that prolonging such feeding produces cirrhosis of the liver. The type of diet definitely modified the mortality rate and the character of the lesion. Diets high in fat increased the severity of hepatic damage, while diets high in carbohydrate and protein and low in fat increased the number of mitotic figures indicating regeneration. Similarly, Gyorgy² concluded that hepatic injury and fatty infiltration are definitely determined by dietary factors. He found that the addition of thiamine and riboflavin to the diet is of value in reducing the incidence of hepatic damage and that a diet low in casein and moderate to high in fat regularly induces hepatic injury after one hundred to one hundred and fifty days. The use of choline seemed to reduce the incidence of hepatic damage, and the addition of yeast was even more effective in preventing liver injury.

One should not look too lightly on jaundice and hepatitis in its incipient stage and pass it off as a supposed "catarrhal jaundice." Too often the disease may pass beyond clinical control and serious or fatal damage occur.

DIAGNOSIS

Liver dysfunction may be exceedingly difficult to diagnose and in many cases is masked by other clinical syndromes. The loss of appetite, morning nausea, biliousness, constipation, sudden attacks of or prolonged weakness on the least exertion, a tendency to perspire easily, loss of weight, sallow complexion, furred tongue, headaches and vertigo were known to older clinicians as evidences of liver disease. Today the newer knowledge of liver function may establish scientific criteria for old clinical truisms. Jaundice may be below the level for objective clinical manifestations and demonstrable only by serum bilirubin tests. Blood studies usually reveal an increased amount of serum bilirubin (latent jaundice). Liver function tests are discussed elsewhere in this symposium, but the most accurate tests may be negative in the presence of liver disease or one may be positive while others give results within normal limits.

I should like to call attention to one form of liver disease that is not commonly recognized. Until a better name is given, it might be called the "cholecystohepato-hyperglycemic and glycosuric syndrome." This is seen after treatment over long periods for true diabetes. The clinical picture is striking. Usually there is a long-standing history of gallbladder disease, interspersed in most cases with attacks of acute or subacute suppurative cholecystitis. Usually the gallbladder is not visualized. The sugar tolerance is not that of true diabetes but is more like that of liver damage. The urine contains sugar. Ketone bodies are not present and, as a rule, the physician makes a diagnosis of diabetes mellitus. Rarely if ever are there attacks of diabetic acidosis. The patient is usually given insulin even large doses of protamine zinc insulin, with a presumed diabetic diet. In spite of this supposed adequate control

Glycogen breakdown in normal liver (phosphorylation by means of enzymes). Insulin most probably acts in this system.

Amylase breakdown of glycogen in "toxic" liver. Insulin does not act in this system. Dextrose, however, can inhibit the breakdown by mass action.

Fig. 2—Diagram of the breakdown in the liver of glycogen to sugar (glycogenolysis) which is faster than its storage (glycogenesis).

the urine continues to show sugar. Blood studies may reveal high values, even as high as 250 mg. per hundred cubic centimeters, depending on the age of the patient and the duration of the disease. This was seen in 1 of the 6 cases that I observed.

REPORT OF CASE

Mrs. A. S., aged 66, entered the hospital April 22, 1940 with an immediate complaint of a more or less constant dull ache in the right upper quadrant of the abdomen for the previous

¹ Earle, V. J. *J. Exper. Med.* 75: 179-189 (Feb.) 1942.
² Gyorgy, Paul and Goldblatt, Harry. *J. Exper. Med.* 75: 355-368 (April) 1942.

two weeks radiating to the left upper quadrant as well as in the opposite direction and into the back. She vomited several times. This subsided after limitation of her diet. She had lost 5 to 6 pounds (2.3 to 2.7 Kg.) recently. She had been constipated but noted no change in the color of her stools. She had been treated for many years for diabetes. Twenty years before she had had a presumed cholecystectomy. She had seven children and had ceased menstruating twenty years before. The rest of her history was not significant.

The patient looked her age on physical examination. Her blood pressure was 150 systolic and 70 diastolic, her temperature 99.2 F, her pulse rate 90 and her respiratory rate 20. There was no scleral icterus. The mouth was edentulous but otherwise normal. Aside from a systolic murmur at the base, the heart showed no unusual changes. The lungs showed evidence of moderate emphysema. There was an ancient scar in the right upper quadrant of the abdomen, exquisite tenderness was present in this region and a large mass was felt here apparently connected with the liver, and this was also tender. The spleen was barely palpable.

The clinical diagnosis was recurring gallbladder disease in a patient who presumably had had a cholecystectomy twenty years before.

Wassermann and Kahn reactions of the blood were negative. The blood count showed erythrocytes 4,380,000, hemoglobin content 70 per cent (Sahli) and leukocytes 21,000, with a differential count of neutrophils 82 (stab cells 16 and segmental forms 66), 1 eosinophil, 15 monocytes and 2 transitional cells. Blood chemical analysis showed 244 mg of sugar, 64 mg of nonprotein nitrogen and 14 mg of creatinine per hundred cubic centimeters. The icteric index was 5. Total cholesterol was 193 esters 94 and free cholesterol 99 (47 per cent esters).

The feces were brown and soft with no occult blood. The urine showed no albumin, there were occasional white cells and 0.2 per cent sugar (total for twenty-four hours, 2 Gm.). The flat film revealed a large gallbladder containing multiple radiolucent stones.

The patient had been receiving from 15 to 25 units of protamine zinc insulin daily for five days in the hospital previous to my seeing her.

I was curious about the abdominal mass so I immersed the patient in a tub of warm water to relax the abdomen. At this time the mass was found to be definitely connected with the liver and was either a firm enlarged gallbladder or Riedl's lobe.

The clinical picture resembled that of recurring suppurative cholecystitis with liver damage, and I therefore advised immediate cessation of insulin therapy. The diet was kept at 200 Gm of carbohydrate, 50 Gm of fat and 75 Gm of protein (her weight was 50 Kg.). She was then given daily 200 Gm of 10 per cent dextrose in water intravenously. While the urinary sugar output definitely increased (shown in the table), ketone bodies were not present in the urine and even with the large amount of intravenous dextrose a gradual reduction occurred in the amount of sugar spilled over into the urine. The level of the blood sugar also eventually came down sharply, in spite of intravenous administration.

Fourteen days after this therapy was instituted the patient was considered to be in good enough condition for surgical operation. An empyema of the gallbladder with multiple stones, multiple adhesions of the gallbladder to the hepatic flexure, transverse colon, duodenum and omentum, and a dilated common duct were seen. Cholecystectomy with exploration of the common duct was performed, but there were no stones in the duct. Recovery was uneventful and finally, with the same diet and without insulin, sugar was not spilled in the urine after the intravenous dextrose was discontinued. This is illustrated in figure 1 and the accompanying table.

COMMENT

Other patients subjected to cholecystectomy showed essentially the same clinical picture. The best explanation of what is going on in the liver is brought out in figure 2. The breakdown in the liver of glycogen to sugar (glycogenolysis) is faster than its storage (glycogenesis).

Since insulin further depletes the storage of glycogen by the liver, owing to its deposition of sugar in muscle tissue, it increases the glycogenolytic process in the liver. The liver is further damaged when its protective mechanism of glycogen reserve is lowered. The hyperglycemia induced by the intravenous dextrose therapy prevents the rapid glycogenolytic manifestation. The process is reversed, the liver therefore stores more

glycogen, the blood sugar level during fasting is lowered, the urinary sugar disappears and no evidence of "diabetes" other than the elevated blood sugar level if that could be called evidence, remains. In some cases with the improvement in the storage of glycogen other liver function returns nearly to normal the blood sugar level returns nearly to normal and no urinary sugar is ever present after cholecystectomy, in spite of continuing the diet used before, with no insulin used at any time in the period studied.

This series of cases serves to emphasize apparently unrecognized liver dysfunction treated as diabetes. The

accurate scientific evaluation of this symptom complex and subsequent cholecystectomy substitute a life of well-being for one of invalidism and continued medical care.

The liver may be a factor in many obscure metabolic phenomena, and more investigations and studies should be directed along these lines.

THE CONCEPT OF LIVER DEATHS

CHARLES GORDON HEYD, M.D.

NEW YORK

In 1922 following a rather prolonged period of clinical observation it became evident that there were certain types of mortality that followed operations on the external biliary system.¹ There were three types of death that followed gallbladder surgery. Later these findings were more formally presented as follows:

GROUP 1—Liver deaths associated with hyperpyrexia and coma. Death ensues in eighteen to thirty-six hours.

The first group is composed of patients who have had a comparatively simple gallbladder operation. The patients were usually obese and gave a history of chronic gallbladder disease. Preoperative study did not reveal any contraindication to surgical intervention. Following cholecystectomy the recovery from the anesthesia was slow, in fact, the patient never did emerge fully from the anesthesia. In four to six hours after the return to the ward the patient was in a semicomatose state that passed rapidly into stupor and coma, with a rapidly ascending temperature to 105-106 F.

GROUP 2—Liver deaths associated with a constantly diminishing jaundice and the secondary development of stupor and coma, the final clinical picture similar to a "cholemic death" in cirrhosis of the liver.

The second group is essentially different in its clinical manifestation. The patients have had a chronic, severe type of biliary duct infection with obstructive jaundice and usually have had a previous cholecystectomy. The common duct obstruction has been relieved by drainage of the common duct and the postoperative condition of the patient has been somewhat but not completely satisfactory. After a variable period four to seven days, the patient falls into a stupor, oliguria develops and the patient dies in coma with hyperpyrexia.

GROUP 3—Liver deaths associated with and complicated by a secondary renal degeneration of severe degree.

The third group lacked two essential clinical features of the first two groups. There was an absence of the hyperpyrexia and coma. The patients within this group have had a chronic, severe type of gallbladder and duct disease. Forty-eight hours after operation there was a distinct vasomotor collapse and a continuous and increasing degree of oliguria, with a pronounced elevation of the nonprotein nitrogen. Anuria finally dominated the clinical picture, with death. This third group embraces the dual caption of hepaticorenal syndrome.

It was realized at that time that there was no authoritative foundation for these clinical syndromes except

that based on clinical observation. The following factors, however, were apparent: 1 Postmortem examinations uniformly revealed no adequate cause for death except such associated changes as were incident to the age of the patient. 2 Most of these patients had a relatively good body chemistry before operation and nearly all of them had had adequate preliminary preoperative laboratory studies which indicated that there was no basic defect in kidney function. 3 This group of patients were gravely ill and the majority of them died. 4 All of these patients developed major renal complications if they survived long enough. Group 3 always developed varying degrees of oliguria which preceded the final development of an almost complete anuria. 5 The clinical status of the patients exhibited all gradients of severity. 6 The hyperpyrexia group invariably died in coma as the result of a fulminating toxic process. 7 The ultimate mechanism of death, I believed, was a chemical disturbance within the liver. In an earlier experience the type of mortality under discussion was confined entirely to patients who were operated on for disease of the gallbladder or biliary tract, and the phrase "liver deaths" was coined to express this concept.

In an evolutionary sense the liver is, with the exception of the primitive gastrointestinal tube, the oldest physiologic organ. The liver is able to protect itself and does so continuously from almost every type of intoxication whether introduced through the gastrointestinal tract or distributed through the vascular system. In some way or other the liver is concerned with practically every function in the body. It is an interesting and arresting thought that this organ, which under the ordinary conditions of life is so adequately endowed for the protection of the organism, fails if and when it must combat the by-products of the degeneration of its own cells. The mechanism that the liver exercises for the protection of the body apparently fails when the toxins are of hepatic origin. The condition undoubtedly has its origin in the degeneration of individual liver cells. If the process is acute, fulminating, there is a very early death with hyperpyrexia and coma—"liver death." If the process is less severe and the elaboration of the hepatic toxins less rapid, the patient survives until the secondary effects of this toxin are manifest in destruction of renal parenchyma with the clinical picture of oliguria, progressing to anuria, hence the associated mechanism of liver-renal damage—the hepaticorenal syndrome.

On a few occasions it has been noted that in crushing injuries of the liver there was a clinical picture of hyperpyrexia with coma and death. The importance of this fact was not recognized or given emphasis until 1927, when a case was reported of a young woman who had a grave injury to her liver following an automobile accident.² This was followed by hyperpyrexia within the first twenty-four hours and death. Postmortem examination revealed that the cause of death could not have been hemorrhage and that there was a traumatic necrosis of liver tissue with a high degree of parenchymatous degeneration of the cortex of the kidneys—hepaticorenal syndrome.

Another very interesting observation was the degree of liver damage associated with intra-abdominal infec-

tions⁴ The mechanism of liver damage was by either the portal system or the intrahepatic bile canalicula and in patients presenting any degree of such liver damage there was almost always an associated change in the capsule of Glisson with the lying down of fibrous tissues capable of being demonstrated as white opaque areas over any or all portions of the liver, more particularly in the area extending out from the gallbladder fossa

Significant experimental work was done by Boyce,⁵ who prepared various emulsions of liver tissue from patients dying of this complication, he demonstrated that alcoholic extracts of such liver tissue when injected into dogs did not produce the complication and aside from some slight indispositions in his animals no bad results obtained on the contrary, when an aqueous solution was injected into animals parenchymatous degeneration of liver cells with similar changes in the convoluted tubules of the kidney was found This picture in the experimental animals exactly simulates the picture obtained post mortem in patients who die of the hepatorenal syndrome

It is also interesting that clinical pictures identical with those originally described have been reported as arising with or without surgery and in conditions other than those associated with operations on the biliary apparatus It is also advanced by competent observers that the basic mechanism in these liver deaths is a fulminating overwhelming infection Careful examination of the evidence submitted by the proponents of this idea fails to carry with it sufficient reasonableness as to make it acceptable

Gross traumatic necrosis of liver cells or some unknown mechanism of injury of liver cells may produce an extremely powerful toxin as the result of necrosis of liver cells, and this in turn exercises a specific effect on all parenchymatous tissue and more particularly on the epithelium of the convoluted tubules The toxin, if such it is, does not arise per se in the kidney but arises in the liver and the renal sequelae are the end result effected by the excretion of foreign protein

In group 1 the patients who died in eighteen to twenty-four hours with hyperpyrexia and coma did so because of an overwhelming toxemia and they did not live long enough to develop what I believe to be the inevitable secondary renal changes The persons in the other two groups were able to sustain life for a longer period than in group 1 with the result that on autopsy they invariably exhibited the secondary changes in the renal tubules in the form of cloudy swelling and necrosis It is this peculiar chemical sequence that gives rise to the hypothesis that while the liver has the most extraordinary ability to protect the organism from injury arising from the gastrointestinal tract, through the portal circulation, or from injury coming to it via the systemic circulation, it does not have the same ability to protect itself from necrosis of its own liver cells, and the absorption of the by-products of liver necrosis will lead to death in a relatively short time with hyperpyrexia and coma or a death of later sequence when liver degeneration is associated with degeneration of the kidney

ABSTRACT OF DISCUSSION

ON PAPERS OF DR MANN, DR MATTER, BALTZ, MAKION
AND MACMILLAN, DR JOHNSON AND BOCKUS,
DR TORTIS AND DR HIRSH

DR CHESTER M JONES, Boston If Dr Mann's observations can be transferred from animal experimentation to human beings, the fact of selective diversion of material from the portal stream in various types of liver is of extreme importance, and it may help to explain the fact that the oral tests of liver function differ distinctly from the results obtained when material is given intravenously It is quite possible that comparative values between two such methods will be of real help Dr Mann implied the wisdom of putting the liver under strain either by exercise or by the intake of food in order to obtain the most definitive results in covering the function The factor of safety of this organ is so great, it is perfectly obvious in minor changes that no liver function test gives any information, but if one puts extra strain on the organ the minor differences may be brought out The insistence of Dr Matter and his collaborators on finding normal figures cannot be overemphasized The fact that there are wide variations within the normal has been too generally overlooked Drs Johnson and Bockus say that 0.5 mg of bilirubin per hundred cubic centimeters may not represent an abnormal figure Certainly it is unwise to carry out too fine distinctions when minor differences may well fall within normal limits Liver function tests are not diagnostic, they are not yet delicate enough Their chief value is that they confirm a clinical diagnosis or determine progress The surgeons are using large amounts of sulfonamide compounds intraperitoneally, and no doubt the rapid absorption of these through the portal system at times produces serious liver damage, which may complicate the operation for which the patient came One effect is a dangerous prolongation of the prothrombin time In some cases there is jaundice in addition When the portal blood flow is interfered with either by fibrosis, as occurs in cirrhosis, or by other conditions in which the liver is damaged, the powers of repair are damaged Because of interference with portal blood flow, ascites may develop This is not the case and I think it should be stressed definitely that ascites is an evidence of liver failure rather than of increased portal blood pressure and is due fundamentally to hypoproteinemia

DR J P SIMONDS, Chicago Dr Mann's approach to the study of the liver through the door of morphology is interesting and significant It should be borne in mind that the liver and every organ in the body perform their functions through the medium of a specific structural pattern Morphology, or structure, is therefore the foundation for a complete study of the effects of disease on any organ The structural modification induced in any organ by disease will obviously influence its function The functional disturbances that accompany disease can be adequately understood only if they are studied in connection with the characteristic structural changes Amebic abscesses of the liver are far more common in the right than in the left lobe of this organ On numerous occasions I have observed atrophy of the left lobe of the liver particularly the portion of it that lies to the left of the falciform ligament It would be interesting to know whether there is any relation between this localized atrophy and the streamlining of the circulation through the liver Dr Matter and his collaborators have rightly emphasized the need of more reliable standards for tests of hepatic function Dr Mann not only has made clear the reason why standards need to be revised but also has furnished the reason for a variation in results of such tests when the test material is given in different ways It is significant also that in a paper now in press Hepler and Gurley have shown that there is a close correlation (correlation coefficient as high as 0.875) between the weight of the patient and the quantity of benzoic acid excreted as hippuric acid In this test there is no rigidly fixed standard, but results for any patient must be evaluated in connection with his weight

DR HENRY A RAISKI, New York Abnormal liver function tests in persons below 60 years of age may be normal for persons above this age range The age factor should be taken into account Dr Newman and I have made a study of various

liver function tests. We studied the cholesterol partition, cephalin flocculin tests, bromsulphalein and oral and intravenous hippuric acid tests in a group of so called normal persons above 60 years of age. In nearly all of the subjects thus far studied at least one test was positive. In reference to Dr. Portis's mention of vitamin B₁₂, we found porphyrinuria comparatively frequently in these persons of normal age. A woman of 53 gave a history of having consumed much alcohol for many years, loss of weight and intestinal bleeding. The liver was enlarged and the hemoglobin was 57 per cent. Cancer of the intestinal tract was ruled out. On proctoscopic examination, with the instrument inserted to a depth of 6 inches, varicosities were noted. This finding is not often emphasized as confirmatory evidence of the presence of cirrhosis of the liver. These varicosities in conjunction with the clinical and laboratory data, made the diagnosis of cirrhosis of the liver a certainty. This simple diagnostic procedure might be helpful in suspected cases of cirrhosis especially when they do not present a typical textbook picture.

DR. MOSES PAULSON, Baltimore. The interpretation of abnormal liver function tests in nonsurgical patients without jaundice and without clinical evidence of liver disease as indicative of early or occult hepatic disturbances of clinical significance should be accepted with great caution. Under the conditions set forth the tests themselves are open to question. Controls—with one exception by Mateer—have been done with single, not with multiple, tests and chiefly in the young, almost always, in suspected disease. Multiple tests are employed and usually in older persons. When in the control study using multiple tests Mateer encountered unexpected hepatic dysfunction, he discounted such results as being falsely positive because of too sensitive tests. This may or may not be so. Occult hepatic dysfunction or subclinical hepatitis as indicated by abnormal liver function tests have been reported in peptic ulcer, rheumatoid arthritis, skin disorders, neuroses and psychoses. Wyler and I have found that more than 64 per cent of those with dyspepsia without historical cause for liver disease had hepatic dysfunction by at least one of two or more tests used. I used to think that abnormal tests were significant under these conditions, indicating occult hepatic dysfunction of subclinical hepatitis, until this study was completed. When we consider this widespread evidence of liver dysfunction as determined by tests and compare it with the relative infrequency of clinical hepatitis or cirrhosis, several questions arise. Do the tests actually measure liver dysfunction under the circumstances referred to? Are not some of the tests already too sensitive? If the tests actually measure liver dysfunction, does it not seem that such information is not of great import in view of what rarely happens, namely liver disturbance of clinical significance? What has been said is not to be confounded either with tests used in confirmation of clinically evident liver disease or to determine its progression or regression or in the differential diagnosis of jaundice.

DR. JOHN G. MATEER, Detroit. Most of our normal control individuals, studied with the various newer liver function tests, ranged between 25 and 35 years of age. There were a few persons included in this normal group who were between 35 and 45 years. I am not surprised that Dr. Rafsky found a tendency toward the development of positive liver function tests in elderly persons involving at least some functional impairment of the liver, since other organs and organic systems also tend to deviate from normal in elderly persons. The all important point to emphasize regarding liver function tests is that they should be interpreted properly. We believe that they should always be interpreted only in relation to the clinical, x-ray and other laboratory findings if a reasonably accurate total diagnosis is to be attained. We also believe that, in the determination of the normal standard for any test by the study of normal control individuals, one should be conservative and allow a margin in drawing the line of demarcation between normal and abnormal. We do feel that there is a practical advantage in determining the lesser degrees of impaired liver function, which are not associated with permanent, serious and persistent liver disease. One of the best illustrations of this point is found in the gallstone cases referred to in our paper. It is certainly an advantage to know before operation which of these cases present

impairment of liver function, so that the benefit of special preparation for operation may be given.

DR. THOMAS A. JOHNSON, Philadelphia. We anticipated Dr. Jones's thought about the matter of the level of serum bilirubin which we accepted as representing hyperbilirubinemia. I should go further and say that the van den Bergh reaction is entirely unreliable in that range and that photoelectric cell determinations of direct serum bilirubin are more accurate.

DR. SIDNEY A. PORTIS, Chicago. Dr. Mann's discussion regarding the repair of liver damage taking place through the arterial rather than the portal system supports the contentions of those who maintain that intravenous therapy is far superior to that given by mouth. This is especially true in disturbances of glycogen metabolism. One cannot get sufficient concentration in the portal vein at any one time to be of benefit in liver damage, while the hyperglycemia produced by intravenous dextrose is sufficiently high to spill over the increased threshold to nourish the liver cell. The series of patients that I have presented have been treated for a long period of years as diabetic, with insulin and diet, and still could never be made sugar free. A more careful evaluation of these patients revealed that we were dealing with liver damage manifested by increased amolytic activity in the liver cell which was caused by disease of the gallbladder. Therefore the withdrawal of insulin the giving of intravenous dextrose and subsequent cholecystectomy brought about a return to near normal in their sugar metabolism. I agree with Dr. Jones and have seen some untoward reactions from the indiscriminate use of sulfonamide compounds. I should like to call Dr. Paulson's attention to the fact that we are not dealing with end results but with subclinical disease, and we hope by these manifestations and tests to prognosticate what might later happen to a patient. Many patients with obscure gastrointestinal symptoms may have occult liver disease without noteworthy objective findings. We should investigate the possibility of hepatitis, and treatment should be instituted long before outspoken liver disease has developed in order to prevent irreparable damage.

DR. DWIGHT L. WILBUR, San Francisco. Dr. Jones raised the question of the incidence of parasitism and particularly of infection with liver flukes, among the patients who came under our observation. We found infection in only 1 case, the parasite was *Ascaris lumbricoides*. There are many problems in relation to the geographic distribution of primary carcinoma of the liver and particularly to the frequency of it among Chinese, Japanese, Filipinos and members of the Bantu and certain races of South Africa which remain to be solved and which may give significant information regarding the etiologic or predisposing factors of the disease. Undoubtedly in certain parts of China the high incidence of the disease is due to infection with the liver fluke. In other countries the incidence of parasitism is identical in patients who have primary carcinoma of the liver and those who do not have it. It is not unlikely that in Japan the widespread use of "butter yellow," a dye used to color butter, may account for the high incidence of the disease, for it is well known that in the experimental animal this substance is definitely carcinogenic. The importance of dietary deficiency as a predisposing factor of primary carcinoma of the liver is not clear, but in experimental animals it may be an important factor predisposing to the disease.

DR. VIRGIL H. MOON, Philadelphia. One feature discussed by Dr. Heyd deserves more emphasis. I too have seen that hepatorenal syndrome, the so-called liver deaths, and have been keenly interested in their mechanism, not as related to liver injury, but as related to another syndrome, that of shock. These patients die with the shock syndrome characteristically manifested clinically, and the characteristic pattern of visceral pathologic changes is seen post mortem. A highly important item is the evidence of renal insufficiency among those patients who lived several days. It is now recognized that shock occurs in varying degrees and with varying severity. Those with shock of maximal degree may die promptly or within twenty-four hours, those with shock of minimal degree may recover, but the intermediate group in which a sublethal degree of shock persists over a period of time regularly manifest progressive renal insufficiency. Observations and studies on this point will be published soon.

SUBDURAL HEMATOMA AND EFFUSION AS A RESULT OF BLAST INJURIES

SECOND PRELIMINARY REPORT
DIAGNOSIS BY PSYCHIATRIC EXAMINATION

LIEUTENANT COMMANDER WALTER D ABBOTT

MC-1(S), UNITED STATES NAVAL RESERVE

LIEUTENANT (J g) FLOYD O DUE

MC-1(S), UNITED STATES NAVAL RESERVE

AND

LIEUTENANT (J g) WILLIAM A NOSIK

MC-1(S), UNITED STATES NAVAL RESERVE

In this series of 10 patients with subdural hematoma and effusion due to blast, definite neurologic findings have been infrequent or minimal. As a result, some of the patients had repeatedly been considered to have a "functional" condition, and such diagnoses as "psycho-neurosis," "war neurosis" and "traumatic neurosis" had been made. Several had been classified as having "post-concussional" states.

Should this practice be general, it is evident that many will be medically discharged from the armed services with relatively curable organic lesions. The social aspects of such a situation are extremely important, to say nothing of the damage to the personality, future adjustment and earning power of any such patient. He will be considered as "neurotic" or "shell shocked" and in his disabled condition may well become a public charge. Furthermore, it is probable that prolonged presence of a subdural hematoma or effusion will result in permanent cerebral changes and mental deterioration.

It is therefore imperative that every possible facet in our diagnostic armamentarium be exhausted to rule out the presence of these conditions in patients who have been exposed to blast. In our experience, careful psychiatric examination with the use of specialized psychologic testing has been more successful as an indication for pneumoencephalography than the usual neurologic criteria.

PSYCHIATRIC EXAMINATION

The clinical picture presented by these organic cases is different qualitatively from psychoneuroses with anxiety hysterical states. In the latter, extreme restlessness, motor activity, subjective tension, nightmares and insomnia are prevalent. Loud noises, sounds of airplane motors and exhaust explosions are "triggers" sending them into profound anxiety. Objectively they may demonstrate signs of sympathetic overstimulation with hyperventilation, tachycardia, vasomotor flushing, dilated pupils and cold, moist and discolored extremities. Intellectual impairment is not present, as demonstrated by various test procedures.

The subdural cases, to the contrary, present one of two syndromes. In the most frequent syndrome, there is rather pronounced retardation in intellectual activity and personality interrelationships. The face is one of dulness with but little play of facial expression. The emotional tone has the "feel" of dulness or vacuousness. The attention, during the interview, is impaired and the response times are slow. Answers to questions are remarkably barren in description and detail. The whole

approach to life situations, as exemplified by the dynamics of the interview situation, is one of superficiality and attempt to "get by" without complicated mental activity. These patients are not dramatic in their assertions of headaches and other complaints.

The most graphic characterization might be made in the terms of pressure or "push." Patients with subdural lesions are noted for complete lack of push and initiative, whereas patients with an anxiety or traumatic neurosis give the impression of nearly overwhelming pressure. The former may state day after day that they have a headache but register no particular surprise nor make requests for attention when treatment is not given. The contrast of the neurotic with the intensity and demanding air of his complaints, is well known.

The less frequent syndrome occurs in those cases of longer duration and demonstrates the more classic picture usually associated with the organic reaction types. The most striking feature is the impairment of inhibition or restraint producing a euphoric and sometimes facetious air. Motor restlessness with exaggerated mannerisms and gesticulations may be prominent. The emotional tone has the raw "feel" of the organic type with lability and explosiveness. Vasomotor flushing of the face and increased neuromuscular tension can be seen as somatic evidence of quickly stimulated rage reactions. The voice is too loud for the size of the room or for the distance between the examiner and the patient, and laughter is stimulated frequently by the patient's own remarks. The patient may assume unusual liberties in the interview situation, demonstrating poor judgment in interpersonal relationships. Undue productivity, unusual expressions of hostility, self aggrandizement and frequent reminiscences may be part of the lack of restraint.

Definite organic intellectual defects in the form of distractibility, memory failure, perseveration and repetition, circumstantiality and "overparticularization," or too much attention to unimportant details may be present. A mild motor aphasia with hesitation on certain words or with difficulty in repeating test phrases may support the impression of organic brain disease.

USE OF PSYCHOLOGIC TESTING

The routine means of gross psychologic testing may suffice in many instances particularly when correlated with the clinical picture that has been described. The ability to perform complicated calculations may or may not be impaired and care must be used in adjusting the degree of complication to the original level of intelligence and attainment. The recall of digits forward may not be impaired as several patients who had other prominent organic characteristics were able to return eight digits. The reversing of digits, however, represents a higher order of cerebral activity and is likely to furnish added evidence in favor of an organic syndrome. For instance the recall of eight digits forward and only three in reverse represents an inconsistency. The ability for subtraction of sevens from one hundred serially is but slightly impaired in some cases. The organic element may manifest itself by fatigue, with one or two mistakes near the end of the procedure.

Probably more important than the actual figures obtained on the foregoing testing is a qualitative analysis of the patient's performance. Slow response times, poor powers of concentration and emotional upset with rage reaction when confronted with failure may point toward an organic condition.

SPECIALIZED TECHNIQS

Rorschach Test—The Rorschach studies are as yet incomplete and dilation of this method of diagnosis is planned for the future. However, this technic can be an excellent diagnostic aid in borderline and puzzling cases. A fairly characteristic picture is expected in the "dull" syndrome similar to the findings in intracranial tumors by Harrower-Erickson.¹ In differential diagnosis the anxiety and conversion neuroses are likely to give a typically neurotic performance with color shock, lack of human movement and the predominance of animal movement over human movement. Intellectually production is likely to demonstrate some degree of balance between whole and detail responses. The subdural cases, however, demonstrate a lowered productivity with from eight to fifteen responses predominantly of the popular "easy" whole variety. There is little attention to detail and no particular color shock. A previously well adjusted personality may be suggested by several good human movement and form-color responses. Interpretatively the performance can be characterized as a superficial, rather vague adjustment with little drive toward an analytic survey of the environment. Reduced productivity and originality go along with the lack of initiative and "push" mentioned

Pollack.⁶ The vocabulary test gives an estimation of the original intelligence, as this faculty is not readily affected by organic brain disease. The test in abstraction requires not only actual intellectual preservation for success but also attentiveness and some drive for accomplishment.

In this total of 10 cases 9 demonstrated conceptual quotients in the direction of intellectual impairment, as shown in table 1. It will be noticed that only one, patient 9 (J P), attained a conceptual quotient above 100, and analysis of the scores indicates that his whole level of performance, including vocabulary, is impaired. A total mental age of 12.1 is not in keeping with his former level of adjustment and his rating as corporal. The two officers with conceptual quotients of 93 were considered on close analysis to be in the direction of impairment because of extremely superior intellectual backgrounds above their abstraction mental age of 16.5.

Generally from our experience with these and other subdural hematomas not due to blast we are convinced that the Shipley test is more sensitive to pathologic conditions of the frontal lobe. On the basis of normal abstractive ability we have been able to speculate correctly in advance that a pathologic condition did not seriously involve the frontal lobes.

TABLE 1—Results of Tests in Ten Cases

Patient	Diagnosis	Vocab ulary	Abstrac tion	Total	Vocab ulary Mental Age	Abstrac tion Mental Age	Total Mental Age	Conceptual Quo- tient

before rather than an absolute dearth of ideation as a careful testing of the limits will demonstrate. In those with impairment of restraint, a more classic organic picture may be obtained with gross impairment of abstraction demonstrated although the degree of impairment necessary to produce five or more of Piotrowski's² signs of organic brain disease is seldom expected.

SHIPLEY-HARTFORD RETREAT TEST FOR
INTELLECTUAL IMPAIRMENT³

The most useful single instrument has been the Shipley-Hartford Retreat test for measuring intellectual impairment. The ease of administration, scoring and interpretation make it ideal for the military conditions of limited psychiatric personnel. A corpsman can be trained to administer and score the tests with little loss of time by the medical officer.

A complete description of the test with theoretical considerations and methods of standardization has been published by Shipley,⁴ Shipley and Burlingame,⁵ and

In the aforementioned cases a comparison of preoperative and postoperative examinations reveals that 4 patients have made complete recovery as gauged by the conceptual quotient, while 1 has improved. Others have been operated on too recently for evaluation.

Some caution must be used in evaluating the significance of pathologic conceptual quotients. It must be certain that the patient has exercised due effort in taking the test. Other conditions in this age group, such as schizophrenia and severe depression often demonstrate a low conceptual quotient but these are usually eliminated easily by clinical study. In differentiating between organic injury and neurotic states there should be no serious discrepancies in the latter between the vocabulary level and the ability to perform abstractions. In cases similar to case 9, in which the impairment is so great that all the scores are very low, a comparison should be made between the mental age level and the previous adjustment, life attainments and education. Such a patient is likely to have other striking abnormalities on psychiatric examination.

REPORT OF CASES

CASE 3—R T C corporal U S M C demonstrates the "dull" syndrome. This patient sustained shrapnel and other wounds from blast injury while in action against the enemy in the Pacific area. He was unconscious for an indefinite period of time and "hazy" for several days. Following improvement from the shrapnel wounds he continued to complain of

occipital headaches, dizziness, nervousness and nightmares. Nausea with vomiting was frequent, and a board of medical survey considered that he had a traumatic neurosis. He was therefore transferred back to the continent. Here physical examination demonstrated perforation of the right ear drum and multiple recent scars of high explosive wounds over various portions of the body. The only positive neurologic signs were bilateral nystagmus, a mildly positive Romberg sign and slight dysmetria on the left finger to nose test. On psychiatric

examination he presented a facies of dulness with ideational retardation. His attentive powers were impaired. He developed a rage reaction when he found that he could not subtract sevens from one hundred serially. He could return only five digits forward and three in reverse. He attained an intelligence quotient of 98 on the Otis self-administering test, intermediate form A. This, compared with a vocabulary mental age of 182, an abstraction mental age of 102 and a conceptual quotient of 59, indicated a superior original intelligence with definite intellectual impairment.

The Rorschach psychogram is shown in the accompanying chart. The psychogram demonstrates the findings described before with low productivity, slow response time and an over-emphasis of easy and popular whole responses. The personality configuration, although barren, is not that of a psychoneurotic condition. Three human movement responses and one form-color response in this setting give evidence of a previously well adjusted personality. Statistically there are only two of Piotrowski's signs of organic deterioration.

Pneumoencephalography revealed a filling defect in the right frontotemporal area with shift of the ventricular system to the left. Craniotomy by means of perforator opening in the right superior temporal area revealed a tense and blue dura. When this was incised, several ounces of old blood and yellow fluid escaped.

He has made an uneventful recovery. A Shipley-Hartford Retreat test performed ten days postoperatively revealed the results shown in table 2.

TABLE 2—Results of Shipley-Hartford Retreat Test in Case 3

	Score	Mental Age Level
Vocabulary	32	178
Abstractions	24	142
Total	56	163

Conceptual quotient 80. This result is still in the direction of impairment but is evidence of improvement.

CASE 8—C S M, lieutenant (j g), U S N R, presented an example of the syndrome described with impairment of restraint. He was rendered unconscious for two hours by the explosion of a ship 100 yards distant, Dec 7 1941. After returning to consciousness he was confused and had a violent headache for several hours. As there was much work to be done, he forgot about his own difficulties and did not report for hospitalization. He experienced a questionable convulsive seizure on April 7 1942 and was given a thorough clinical and laboratory study. Physical and neurologic examinations were negative. One medical officer noted that the patient seemed to be mentally confused. Spinal puncture revealed an initial pressure of 225 mm of water but total protein was

20 mg per hundred cubic centimeters. Roentgenograms of the skull were negative. It was decided that a diagnosis of epilepsy was not justified on the evidence at hand, and the patient was returned to duty. He was again admitted for hospitalization on November 10 following definite convulsive seizures with tonic and clonic convulsions, tongue biting and postseizure confusion and weakness. Neurologic examination was again negative. The diagnosis of epilepsy was established and the patient was transported to this hospital for a pneumoencephalogram.

Here the patient again demonstrated a normal neurologic examination. He was definitely abnormal on psychiatric examination, however, and a positive diagnosis of organic brain syndrome could be made. He displayed pronounced hyperactivity with exaggerated mannerisms and gesticulations. Emotional lability was definite, a basic euphoria being quickly and momentarily replaced by rage reactions and depressions of mood. His restraint and judgment were greatly impaired as demonstrated by his interpersonal relationships during the interview. His voice was too loud and he frequently laughed at his own remarks. Intellectually he was circumstantial and repetitious and demonstrated automatic phrasing. He dwelt on inconsequential reminiscences of his past. He gave a history of increasing impairment of concentration, memory failures and inadequacy in his work as an engineer. He expressed a feeling of insecurity because of his awareness of this inadequacy and general lowering of mental efficiency.

Although his conceptual quotient on the Shipley-Hartford Retreat test was 93, his abstraction mental age of 165 did not conform to his professional and previous university standing in subjects requiring exquisite abstractions. Pneumoencephalograms demonstrated a definite filling defect in the left frontal region. Surgical exploration revealed an old subdural hematoma in that area.

COMMENT

It is planned to present a complete clinical and psychiatric study of these and succeeding cases in the future. Follow-up studies will be made as practicable. Electroencephalography will be utilized as a further diagnostic aid when facilities permit.

SUMMARY

Early differentiation of subdural hematoma or effusion from psychoneuroses, traumatic neuroses and "postconcussional" states is important individually, socially and economically.

A careful psychiatric examination can demonstrate intellectual impairment in cases of subdural hematoma or effusion despite negative neurologic examination.

Intellectual impairment in blast cases with or without positive neurologic findings is an indication for a pneumoencephalogram.

The Shipley-Hartford Retreat test is an effective instrument in the diagnosis of subdural hematoma or effusion.

Indigestion in Later Life—The arteriosclerotic patient has thickened vessels, often hypertension and tardy digestion. The management of this type of indigestion is largely hygienic and dietetic, being calculated to relieve the burden of digestive work. The treatment of such a case would begin with a complete rearrangement of the diet, lessening protein intake and fats, and using foods which are readily digestible. Another type is found in the cardiac individual, particularly of the angina or coronary type, on the one hand and the individual who has defective cardiac function with a tendency to decompensation on the other. These patients suffer from flatulent indigestion and large indigestible meals which embarrass the heart and may produce an attack. Small digestible meals and particularly avoidance of a large liquid intake are the fundamental principles to be followed.—Rehfuß, Martin E. *Indigestion: Its Diagnosis and Management*. Philadelphia: W. B. Saunders Company, 1943.

ROLE OF THE ANAL GLANDS IN THE PATHOGENESIS OF ANO- RECTAL DISEASE

MALCOLM R. HILL, MD
LOS ANGELES

E. HAROLD SHRYOCK, MD
LOMA LINDA, CALIF

AND
F. GEORGE REBELL, MD
LOS ANGELES

Medicine today has come to accept as rational therapeutics the surgical treatment of anorectal disease. This common acceptance of the application of local removal and drainage of diseased tissues in or adjacent to the bowel outlet is not limited to infective processes. One of the common rectal problems from the standpoint of diagnosis and treatment is fistula in ano. Fistulas occur in the various age periods with an increased incidence in adult life. The fact that it is always associated with some degree of abscess formation predetermines the infective nature of this disease process. The tendency of this infective lesion to tunnel through the anorectal tissues, involving adjacent structures and following a multiplicity of patterns with more or less self-limited regional manifestations, but not always communicating with the bowel, stimulated our interest to make a further study of the anatomic background of this problem.

It has been surmised that the system of anal glands somehow acts as a predisposing factor in the production of infectious lesions which develop in the perirectal tissues. It has been presumed that the infection finds its way through the anal wall by way of these glands, however. The nature and extent of this glandular system has not been adequately studied, as shown by a survey of the literature dealing with the problem and of the textbooks concerned with its clinical and therapeutic aspects. Quite obviously, there is no clear conception as to the part played by these glands in anorectal disease. It is our purpose to present in this study the results of our investigation into the embryology and histology of this gland system and to point out the part that it plays in local disease processes.

REVIEW OF THE LITERATURE

Interest in the existence and function of the anal crypts dates as far back as 1732. At this time Winslow¹ recognized their presence and described them as "semilunar lacunae." About the same time (1738) Astruc² in his treatise on fistula in ano refers to the anal crypts as short ducts or lacunae which appear to convey a "viscid humor."

In 1888 Bodenhamer,³ summarizing the observations of Coats (1841), Gibson (1850) and Gross (1856), described these anal crypts as being foramina and cavities with communicating follicles. These crypts, he claimed, when excited, irritated or chronically inflamed become relaxed, weakened, enlarged and elongated,

thereby losing their contractile power and permitting foreign bodies to enter the pouches, thus favoring production of the disease in question.

It was not until the year 1914 that Franklin Paradise Johnson⁴ published his monumental treatise on "The Development of the Rectum in the Human Embryo" and illustrated their structure and location by reconstruction. His studies laid the basis for our present knowledge on this neglected subject. He demonstrated the existence of anal ducts and their glands in the various stages of embryonic development.

More recently, however, Tucker and Hellwig⁵ confirmed by examination of diseased tissue removed at operation and by study of embryos of representative vertebrates the constant occurrence of branched tubular ducts as "preformed" structures. These ducts did not seem to be the result of any process of degeneration but were presumed by these investigators to be the vestigial remains of large glands found in the lower animals. They assumed that the crypts of Morgagni were not by themselves responsible for the frequency of anal infection but that infection originated as a rule in preformed tubules which are called anal ducts.

Gordon-Watson and Dodd⁶ refer to the anal glands as probably "vestigial" remains which "often lose their connection with the anal glands by obliteration of the ducts during development, and that in some instances when the duct is patent, infection from the anal canal takes place."

The recent observation by Robert Scarborough⁷ of a primary carcinoma in the incomplete canalized or "rudimentary" remains of the anal glands served to focus our attention once more on this important problem.

MATERIALS AND METHODS

A microscopic study was made of the anal canals of 17 subjects: 1 seven month fetus, 5 newborn infants and 11 adults. The tissues from the fetal and newborn subjects were obtained at autopsy, while all specimens from adults were surgical, having been obtained in the course of resections of the colon incident to malignant growths located high in the rectum and sigmoid.

Complete serial sections through the anorectal region were prepared on specimens taken from 2 of the newborn infants, and from 1 of these a scale model (43 diameters) was constructed according to the Harrison method.⁸ A second model (250 diameters) representing a further enlargement of a typical portion of the anal gland bearing area from that shown in the first model was fashioned in clay and cast in plaster. From all other specimens serial sections were made through the region of the anal crypts and those sections selected for study which showed the presence of anal glands.

OBSERVATIONS

In all 17 cases studied anal glands were found extending into the subepithelial tissues in the zone between the anorectal and the anocutaneous line. However, a wide individual variation was noted in the number of the glands, in their structural plan and in the depth to which they invaded the tissues. In the

newborn case in which the entire anal canal was modeled, more than fifty glands were found arising in this area

An average gland may be described as having a duct which opens into an anal crypt. The duct is lined with a stratified epithelium the surface cells of which appear columnar with basally placed nuclei. Communicating with this duct are from one to six slender tubular structures lined with two or three layers of epithelium. These tubular portions of the gland may run either a straight or a spiral course extending either cephalad or caudad. Glands that extend cephalad from the site of their ducts are usually simpler in structure (unbranched tubules) than those which extend caudad. One adult had a gland which extended so far cephalad that its terminal portions reached past the anorectal line into the submucosa of the rectum (fig 1). The glands usually penetrate only into the deeper portions of the submucosa, but in 2 cases in the series they were observed to extend into the substance of the internal sphincter (fig 2). In 1 case the gland was found to penetrate three fourths of the thickness of this muscle. In this series they were not observed in tissues deeper than that of the internal sphincter.

Fig 1—Cephalad extension of anal glands (arrows) beyond anorectal line (broken line), hematoxylin and eosin stain, $\times 19$

An interesting finding was the lack of complete canalization of the terminal portions of the anal glands in 3 of the newborn infants and an obvious cyst formation in 1 adult. In portions of the glands which were not canalized the central part of the solid cord of cells often contained large polygonal squamous cells with very light staining cytoplasm. At the point at which the gland became canalized, the central light staining cells were seen to give way to a typical glandular type of lining epithelium with dark, basally placed nuclei. A careful examination of all the adult specimens failed to reveal any positive instances of uncanalized glandular structures. However, in several specimens the lumen of the gland was very small and eccentrically placed and seemed to branch rapidly in a fashion which closely resembled those glands from newborn specimens which were not completely canalized.

In 4 adult specimens the surface layer of the epithelium lining the ducts of the anal glands presented apical cytoplasmic vacuoles (fig 3). The cells containing these vacuoles gave a positive test with Krajian's⁹ carbol-fuchsin stain for mucin. Another

evidence of secretory activity of the anal glands was furnished by the finding already mentioned in 1 adult case of a cyst of the tubular portion of an anal gland (fig 4). Since this observation was made accidentally in tissue that was being used for the perfecting of a special staining technic, it was impossible to find and

Fig 2—Anal glands (arrows) penetrating internal sphincter. Lower gland has extended three fourths of the thickness of the muscle. hematoxylin and eosin stain $\times 19$

examine all portions of the serial section ribbon. However, in none of the 15 to 20 sections available could any connection with a duct be demonstrated. Additional evidence that this structure had possessed secretory function and had lost its connection with its duct was furnished by the fact that its lining epithelium was flattened and that it was definitely distended with coagulated fluid which stained positively with the mucin stain.

Another finding worthy of note was the presence of lymphocytes in the immediate vicinity of practically all

Fig 3—Epithelium of anal gland showing apical cytoplasmic vacuoles suggestive of secretory function. Krajian's carbol-fuchsin stain for mucin $\times 520$

anal glands. In some specimens this lymphocytic infiltration was slight, whereas in others it was so pronounced as to suggest the structure of lymph nodules. In only 1 patient, an adult, were the lymphocytes found to have invaded the epithelial lining of a gland or its duct. The zone of lymphocytic infiltration that surrounded the anal glands and their ducts was continuous

with that which occurred deep in the epithelium which lines the anal canal and when followed cephalad proved to be continuous with the diffuse lymphoid tissue of the tunica propria of the rectum and colon. Whether the presence of lymphocytes represented a response to an inflammatory process is a question which can be

Fig 4—Cyst formation in anal gland showing (A) location of cyst in internal sphincter (hematoxylin and eosin stain $\times 19$) (B) enlarged view of cyst (Krayian carbolfuchsin stain for mucin $\times 110$)

answered in the negative on the basis of (1) the presence of some lymphocytes in all specimens examined including those from the newborn, and (2) the absence of any significant number of polymorphonuclear leukocytes in the areas under consideration.

Particular attention was given to the presence of smooth muscle in the submucosa of the anal canal in the anal gland bearing area. In harmony with the findings of Fine and Lawes,¹⁰ this study revealed the presence of smooth muscle in this area of the so-called pecten band in each of the 11 adult specimens examined. In 5 of the 11 cases, the band of muscle was very thick; in 2 it was relatively thin and in the remaining 4 it was intermediate in thickness. In 3 of the 11 small smooth muscle fasciculi were diffusely scattered among the larger strands of connective tissue while in the remaining 8 the muscle fibers were more compactly arranged. In the newborn specimens the smooth muscle of the submucosa of the anal canal was found to be in the process of differentiation, muscle cytoplasm being obvious only in scattered areas of the tissues.

CLINICAL APPLICATION

The constant occurrence of anal glands as emphasized by the studies of Tucker and Hellwig and confirmed by our study makes it reasonable to assume as has been done in the past, that infection may be transmitted by the system of anal glands. The fact that there were such decided individual variations of the anal glands

may explain why some persons seem to be more susceptible to anorectal disease than are others. In order to correlate the microscopic changes of anal glands with the development of anorectal disease, consideration must be given to the various successive steps involved in the disease process.

It is commonly recognized that any alteration in bowel habitus is responsible directly or indirectly for more pathologic conditions of the anorectal region than all other possible causes combined. Limited space will permit only a brief consideration of the various possible factors involved in these changes.

Simple traumatic lesions of the anorectal region are the result of an overdistention of the anal canal by the passage of dry or hard fecal matter. Conversely, it is also acknowledged that constant irritation following frequent loose evacuations for long periods will likewise produce a similar condition. This trauma according to Lockhart-Mummery¹¹ is most likely to occur in the posterior midline where the arrangement of the muscle fibers of the external sphincter give the least support. This being the weakest point of the anal orifice, any undue stretching is likely to occur at the posterior commissure, since the fibers supporting this region are not parallel to the anal wall. The next weakest point is at the anterior commissure since relatively few circular fibers are present to give support.

Furthermore, it is recognized that the bowel tract acts as a natural habitat for the commonly known pathogenic and nonpathogenic bacteria. As previously mentioned, under certain stress and strain these organisms from the bowel may invade the adjacent tissues, namely the gland bearing area. In addition to this mode of bacterial activation and a weakened constitution especially in the presence of disease elsewhere in the body, such as infected teeth or tonsils and disease of the upper respira-

Fig 5—Enlarged deep crypt with numerous ramifying anal glands. Lymphocytes are infiltrated around the mucous producing glands. Hematoxylin and eosin stain, reduced from a photomicrograph with a magnification of 73 diameters.

tory tract a decrease in tissue resistance is apt to occur which encourages or enhances the development of infection. Other avenues of activation which affect the gland bearing elements into a state of active localized cellulitis

11 Lockhart-Mummery J P. Diseases of Rectum and Colon and Their Surgical Treatment. Baltimore: William Wood & Company, 1934.

may be brought about not only by direct invasion through the system of anal glands but also by way of the tissues developing as a result of a blood borne origin

Under these circumstances an infective process would be expected to follow the lines of least resistance. Therefore, changes in contour, size and depth of the anal crypts, particularly those situated in the posterior midline or immediately on either side of this area are more frequently found to become involved following continued irritation and trauma. Therefore after infection has invaded the anal crypt its mode of spread and advance would follow a definite microscopic pattern.

One of our specimens (fig 5) clearly demonstrates an enlarged and elongated crypt with numerous ramifying anal glands extending into the muscularis submucosae and It is obvious that infection once set up by trauma or other irritation in such a crypt could continue to spread along the avenues of all the glands present in this structural formation.

Another interesting observation (fig 1) was that of several glands which were noted to extend cephalad beyond the mucocutaneous junction into the submucosa of the rectum. This finding offers a logical explanation of the occasional occurrence of abscesses and fistulas encountered in this region when the primary focus of infection is located in an anal crypt.

Similarly the small unbranched type of duct and gland with its shallow penetration pointing toward the lining of the anal canal in close proximity to the anocutaneous line gives satisfactory reason for the acute infected fissure which becomes chronic and unyielding to ordinary simple measures and which at the time of the operation proves to involve the regional anal crypt.

In the adult case represented in figure 2 the extent of invasion of an anal gland is seen to be deep penetration into the internal sphincter. Some authors have expressed the opinion that the glands may invade even the outer longitudinal muscle. This possibility however was not confirmed by our study. Should this penetration of glandular structures be along muscle bundles or fascial planes it is reasonable to conclude that the zone of spread of infection would include those structures adjacent to this line of cleavage.

In the study of the fetal tissue attention was called to two outstanding details i. e. (1) uncanalized glandular structures and (2) a variation in the thickness of the submucosa and the retarded differentiation of the muscularis submucosae and These findings suggest two possible explanations for the occurrence in adult tissues of isolated epithelium lined cystic formations. The formation of such cysts may be the result of either (1) failure of the cord of epithelial cells to canalize and communicate with its duct or (2) a choking off of certain glandular tubules which have previously invaded the area in which the fibers of the muscularis submucosae and subsequently develop.

The findings noted in one of our adult patients of a cyst with flattened epithelial lining and distended with coagulated fluid which stained positively for mucin provides a basis on which may be explained the development of those abscesses and fistulas which do not communicate with the anal canal. The accumulation of fluid within this cyst (fig 4) suggests that its lining epithelium possesses a glandular function. This assumption of glandular activity is further confirmed by the presence in 4 cases of cytoplasmic vacuoles in the epithelial cells of the anal ducts. Such isolated cysts may serve as a focus for the development of a blood

borne infection in a manner similar to that which occurs in other parts of the body such as the thyroglossal duct and cervical cysts. Trauma to such a cyst may conceivably predispose to abscess formation also.

It has always been perplexing and difficult to explain the existence of primary carcinoma when found in the perianal tissue. A recent case report by Scarborough⁷ pertains to the possibility of primary carcinoma originating in an anal gland. It is conceded in this study that such a glandular cyst as shown in figure 4 might even serve as a nucleus for the development of a neoplasm.

Since the early part of the sixteenth century anatomists have made mention of a "viscid humor" secreted by the anal crypts, yet it has been quite impossible to uncover any literature of the microscopic picture of an anal crypt that demonstrates by special stain or cytologic procedure this particular function. Many authors discuss this matter, referring to the secretory function of the anal glands, particularly in animals⁸ and usually assume that the anal glands of the human being are vestigial⁹. The present study does not bear out the latter assumption. It has been suggested by local pathologists that these glands are active only at certain periods a small number of glands being active at a given time. It is thus assumed that each gland is active by cycles. Special stains applied to the tissues from 3 of our patients gave positive evidence of the presence of mucin either in the cytoplasm of the epithelial cells or in the coagulated fluid adjacent to the epithelium. This observation suggests that these glands are not vestigial but are structures which function throughout life.

SUMMARY AND CONCLUSIONS

While some causal relationship between the anal glands, perirectal abscess and fistula in ano has been presumed to exist, the underlying and developmental and structural basis for this relationship has never been fully established. In this study we have investigated the structure distribution and relationship of the anal glands in 1 seven months fetus, 5 newborn infants and 11 adults.

Anal glands manifested a wide individual variation as to number, depth of penetration and contour. Lack of complete canalization of the terminal portion of the anal glands was observed in 3 newborn infants. In some of the adult specimens the cells lining the anal glands presented apical cytoplasmic vacuoles which stained positive for mucin. The appearance of a cyst of the tubular portion of an anal gland further suggested a secretory function. The presence of smooth muscle in the submucosa of the anal gland bearing area was found to vary in thickness and in stages of development. Variable lymphocytic infiltration was noted in all cases studied and was considered of nonpathologic significance.

Various existing traumatic bacterial and constitutional factors unite to permit infection to spread by way of the anal gland system. The extension of anal glands upward beyond the anorectal line into the rectal submucosa offers a logical explanation of the occasional occurrence of abscess and fistula in this region. The deep penetration of an anal gland seen extending into the internal sphincter points to possible avenues of invasion along muscle bundles fascial planes and adjacent structures to these lines of cleavage. One adult had a definite gland cyst which supports the claim that abscess and fistula may develop without communication with the anal canal. Primary carcinoma originating in

the perianal tissue is possible to occur, perhaps following chronic trauma, with a glandular cyst serving as a nucleus for development. The assumption that anal glands in the human being are vestigial remains and function only in animals was not supported by our observation. Instead, these glands are evidently active as secretory structures throughout life.

ABSTRACT OF DISCUSSION

DR ROBERT A. SCARBOROUGH, San Francisco. Owing to the microscopic nature of the anal glands it has appeared reasonable to assume that infection pocketed in an anal crypt was the causative factor in the development of fistula in ano since every such fistulous tract leads back to the site of such a crypt. This crypt is often of considerable depth, showing evidence of a chronic inflammatory process. It occasionally happens that a fistulous tract as it is followed back from the secondary opening, approaches the epithelium at the mucocutaneous line but no actual surface opening can be grossly demonstrated. This has led in the past to some confusion concerning the origin of such fistulas. I have felt that such glands must be an important factor in the not infrequent development of fistula in ano in young infants whose anal crypts are thin delicate, healthy valves without the evidence of chronic infection found usually in this disease in adult patients. The authors' excellent microscopic studies in the newborn have served to support this belief. This paper has given us the first evidence of the secretory function of these glands.

DR CLAUDE C. TUCKER, Wichita, Kan. This demonstration of the presence of lymphocytes in the immediate vicinity of anal glands which had been shut off from anal ducts may be the answer to the origin of abscess and fistulas which do not communicate with the bowel wall. In our studies the ducts and crypts were excised from diseased tissue. In the past nine years we have studied from a histopathologic standpoint several thousand specimens and seldom did we find the wall of the ducts not diseased and oftentimes we found lymphocytes in the surrounding tissue. In second and third stage hemorrhoids the diseased ducts were found in the pile tissue. When all visible ducts and crypts have been removed at the time of operation it is no indication that others may not become infected. Thus the infected crypt becomes edematous and the papillae become enlarged and sensitive. Many reflex symptoms are often produced from a single infected duct and crypt. Many of the so-called tumors arising at the anorectal line are simply enlarged papillae which have grown out of an inflammatory process which had its origin in an infected duct and crypt. Robert Scarborough reported a case of carcinoma with its origin in an anal gland. We also have had one originating in anal ducts proving that these structures are not free from primary malignancy.

DR MALCOLM R. HILL, Los Angeles. The results of our investigation were derived from anorectal tissues showing little or no pathologic change. The newborn subject was selected for model reconstruction in an attempt to make an accurate count of the number of glands present in the tissues of the anorectal canal. We were able to outline in detail the branched intramuscular glands but in addition to this many single unbranched gland structures. In both the infant and adult specimen studied there was noted a pronounced variation both as to location and as to the number of glands present. Lockhart-Mummery explains why daily or repeated trauma to the crypt line and these adjacent glandular structures is more prevalent in the posterior commissure and secondarily in the anterior anal margin by virtue of lack of support to the muscle structures. While the anal crypt is frequently the port of entry to the numerous ducts and glands, it must not be overlooked that the coexisting cryptitis may be secondary to a primary infection in the anal gland system. Blood borne infection to these gland bearing areas must not be overlooked. The isolated gland mentioned by Scarborough gives a ready explanation of the etiology of the abscess and fistula which has no direct continuity with the bowel. The cyst formation present in this type of glandular

structure predicates the possible insurance risk from trauma in line of duty. Modern war surgery has been confronted with a similar analogy in the recurrence of a pilonidal cyst from experience in a jeep car or tank. Our study has not borne out the idea that these glands are vestigial remains. Secretory activity was shown to be present. Hirschman for years has taken cultures of the secretion or discharge from the anal crypt and found that the derived autogenous vaccine is a valuable therapeutic agent. This would lead one to conclude that the anal gland system is a potent field for focal infection.

MAPHARSIN IN THE TREATMENT OF CONGENITAL SYPHILIS

WITH ESPECIAL CONSIDERATION OF THE INTRAMUSCULAR METHOD OF ADMINISTRATION

GIRSCH D. ASTRACHAN, M.D.

AND

VAN ALSTYNE CORNELL, M.D.

NEW YORK

Mapharsin which was studied and introduced by Tatum and Cooper,¹ was investigated clinically by O. H. Foerster, who made the first report on the use of this drug in antisyphilitic therapy for human beings at the meeting of the American Dermatological Association in 1933. Since then numerous investigators² have published articles on the therapeutic efficacy of this drug as well as on its toxicity. Most of the investigators agree that mapharsin is a good antisyphilitic drug³ and that it is less toxic than nearsphenamine.⁴

The fact that only six fatalities⁵ resulting from the use of mapharsin have been reported, while over

12 million ampules of this drug have been manufactured,⁷ makes this trivalent arsenical very suitable for antisyphilitic therapy.

The value of mapharsen in congenital syphilis was studied by us⁸ as well as by Morgan,⁹ Howles¹⁰ and Wile¹¹ and fairly good results were reported.

The present paper deals with the problem of the efficacy of mapharsen in congenital syphilis experimentation with larger doses and also the problem of local pain following the intramuscular administration of this drug.

Eighty-seven patients were treated, of whom 57 had late congenital syphilis, 11 early congenital syphilis and 19 latent syphilis (adult women in whom mapharsen injections were given intramuscularly). There were 36 cases from the Metropolitan Hospital division of the Welfare Island dispensary (service of Dr. Van Alstyne Cornell), 20 from the Metropolitan Hospital (services of Dr. Van Alstyne Cornell and Dr. Reuel Benson), 21 from the Skin and Cancer Unit (service of Dr. Fred Wise) and 10 from our private practice. Sixty-one patients were females, 26 males. The oldest among the congenitally syphilitic patients was 51 years, the youngest was 4 weeks. Altogether 1742 injections were given (1,507 to congenitally syphilitic patients and 235 to adult patients with latent syphilis). The number of

these cases courses of bismuth and mapharsen administered concurrently were followed by separate courses of bismuth and mapharsen given alternately. There was a slight difference in the serologic results obtained in cases treated with these two methods, that is, in cases treated with the concurrent method the serologic

TABLE 2—Influence of the Methods of Administration of Mapharsen and Bismuth on the Effectiveness of the Therapy in Late Congenital Syphilis

	Total	Improved	Unimproved
A—Patients treated with the concurrent method	17	10 (58.8%)	7 (41.2%)
Patients treated with the alternate method only	25	15 (53.5%)	13 (46.5%)
Concurrent Method Used in			
B—Improved cases	25	10 (40%)	
Unimproved cases	20	7 (35%)	

improvement occurred in 58.5 per cent, while in cases treated by the alternate method a serologic improvement occurred in only 53.5 per cent (table 2).

Among the improved cases the concurrent method was used in 40 per cent, while among the unimproved cases this method was used in only 35 per cent (table 2).

Four cases in which the serologic reaction remained unchanged when the alternate method was used showed a definite improvement when bismuth compounds and mapharsen were administered concurrently.

The effect on the serologic reaction was studied in the cases treated with the alternate method after an average of 19.1 injections of mapharsen and 29.7 injections of bismuth compounds had been given. The group treated with the concurrent method received an average of 22.5 injections of mapharsen and 23.6 injections of bismuth.

Effect of Mapharsen Therapy on the Serologic Reaction in Early Congenital Syphilis (tables 3 and 4).—Ten cases were studied. The dosage of mapharsen given was larger than the one used in the previous investigation.⁸ The maximum dosage was 1 mg per kilogram of weight. Because of the increased dosage of mapharsen, and in order to avoid possible toxic

TABLE 1—Effect of Mapharsen Therapy on the Serologic Reaction of Late Congenital Syphilis

Total number of cases	56
Number of cases in which the serologic reaction was studied	45
Blood serologic reaction reversed partially or completely in	25 (55.5%)
Blood serologic reaction remained unchanged in	20 (44.5%)
Average number of mapharsen injections in improved cases	27.3
Average number of mapharsen injections in unimproved cases	20.1

injections given intravenously was 1,012, the number of injections administered intramuscularly was 730. The dosages given to early congenital syphilitic patients ranged from 0.5 to 15 mg. The dosages in late congenital syphilis ranged from 2 to 30 mg for children and from 10 to 60 mg for adults.

EFFECTIVENESS OF MAPHARSEN THERAPY

Effect of Mapharsen Therapy on the Serologic Reaction in Late Congenital Syphilis (tables 1 and 2).—Fifty-six patients were treated and the serologic results studied of 45 patients. They received an average of 21 injections of mapharsen (dosages ranging from 2 to 40 mg). Among these 45 patients 25, or 55.5 per cent, showed an improvement in their serologic reaction (complete reversal in 8 cases) after they had received 27.3 (average) mapharsen injections. In the remaining 20 cases, or 44.5 per cent, the serologic reaction remained unchanged after an average of 20 injections were given (table 1).

In all cases of late congenital syphilis the mapharsen therapy was supported by injections of bismuth compounds. Twenty-eight patients were treated with the alternate method of administration of bismuth compounds and mapharsen. In 17 cases the concurrent method of administration was used and in most of

reactions, mapharsen and bismuth compounds were given in alternate courses in most cases. Treatment was usually begun with 1 to 2 mg and increased weekly by 1 mg until the maximum dosage was reached (1 mg per kilogram of weight). The average dosage for the improved and unimproved cases was 6.5 mg and 5.9 mg respectively. In 1 case the maximum dosage was 15 mg. If we regard the improvement in case 1 as a very slight one and put it in the group of unimproved

¹¹ Wile U. J. In discussion on Foerster and others.

cases, we may say that 7 out of 10 cases, or 70 per cent, showed a partial or complete reversal of the serologic reaction following the injection of 17.3 mg (average) of mapharsen. (The serologic reaction reversed to negative in 3 cases, table 4.) It is also of significance that in both cases in which the concurrent method of administration of bismuth compounds and mapharsen was used the serologic reaction reversed to negative after an average of 13.5 injections of mapharsen were given.

Spinal Fluid Findings—The spinal fluid was studied in 40 cases. The results of the examinations were negative except in 2 cases. In 1 case (M G), of frequent convulsions, with some change in the colloidal gold curve (1232210000) in an otherwise negative spinal fluid there seemed to be improvement under the influence of mapharsen therapy.

Patient 2 (baby S), whose mother had syphilis, was apparently normal at birth but on the second day of life began to develop respiratory and feeding difficulties and was put under a constant oxygen tent. Because of the positive cord Wassermann test and x-ray findings of the long bones (syphilitic periostitis) it was thought that the broncholarineal collapse might be due to

TABLE 4 (Analysis of Table 3)—Effect of Mapharsen Therapy on the Serologic Reaction of Early Congenital Syphilis

3 Number of cases in which the serologic reaction did not change	3 (30%)
4 Average number of mapharsen injections in improved cases	17.3
5 Average dosage of mapharsen in improved cases	6.0 mg
6 Average number of mapharsen injections in unimproved cases	14.3
7 Average dosage of mapharsen in unimproved cases	5.9 mg

congenital syphilis. Antisyphilitic therapy was instituted. Three injections of a bismuth compound were given followed by twelve injections of mapharsen, starting with a dosage of 0.5 mg and increasing each time by 1 mg until 5 mg was reached. After four months of therapy the spinal fluid, which was strongly positive for syphilis, became completely negative. The Wassermann reaction of the blood was 2 plus. The baby gained 6 pounds (2.7 Kg), became more active and was not listless. However, the patient presented a pronounced hydrocephalus¹² (ventriculographic study of the skull revealed a tremendous dilatation of both ventricles) which increased in size somewhat in spite of antisyphilitic therapy.

Effect of Mapharsen Therapy in Cases of Interstitial Keratitis—Five patients were observed and they seemed to have benefited greatly by mapharsen therapy. In 1 case, in which the condition gradually became worse while sulfarsphenamine injections¹² were being given, there was a decided improvement in the cornea and in vision following ten injections of mapharsen. The second case cleared up almost entirely after five mapharsen and ten bismuth injections were given concurrently. The third patient was readmitted to the Metropolitan Hospital several times because of a recurrent interstitial keratitis. The Wassermann test was persistently negative but the interstitial keratitis improved

each time mapharsen therapy was given concurrently with a bismuth compound. The fourth patient also showed a definite improvement following the alternate administration of mapharsen and bismuth courses. The fifth patient (W G) was admitted to the Metropolitan Hospital with the history of progressive blindness for two months. Concurrent administration of mapharsen and a bismuth compound was instituted and the patient showed improvement after four weeks of therapy. Later on, potassium iodide and boiled milk injections were added to the therapy. The interstitial keratitis was arrested and improved. The serologic reaction, however, did not change following thirty-six mapharsen and thirty-seven bismuth injections.

Congenital Syphilis and Pregnancy—Six patients were observed, one of them is now in the fifth month of pregnancy and is receiving weekly injections of mapharsen without any untoward reactions. Five patients gave birth to normal, nonsyphilitic children after having received throughout pregnancy an average of 12 injections of mapharsen and 13 injections of a bismuth compound given in alternate courses. Both the cord and the blood Wassermann reactions were negative in 4 cases. In the fifth case only the cold serologic test was taken and this was found to be negative. All 6 patients tolerated the injections of mapharsen well and had no untoward reactions with the exception of 1 patient, who developed nausea once, and another who developed pruritus. In 2 cases the injections of mapharsen were accompanied by injections of liver extract without any ill effects on the patients or the course of their pregnancies.¹³

Untoward Reactions¹⁴—The majority of our patients tolerated the injections of mapharsen well and showed no untoward reactions. Among 68 patients with congenital syphilis who received altogether 1,507 injections (1,012 intravenously and 495 intramuscularly) there were 15 who developed some kind of reaction. Altogether 17 reactions were observed. Of these 9 were of a mild character and presented some mild gastrointestinal disturbance such as nausea, vomiting or fever. These reactions occurred generally only once and did not recur after the dosage of mapharsen was diminished. There were 7 delayed reactions in 7 patients. Three developed pruritus. In 2 cases the pruritus did not recur when prophylactic liver extract injections were given.¹³ In the third case the pruritus was not prevented nor alleviated by concurrent liver extract injections¹³ and mapharsen had to be discontinued. Two patients developed erythematous eruptions lasting for a few days. One patient (A H, a boy aged 11 years, weight 83 pounds, 37.6 Kg) developed jaundice following 10 mapharsen injections (7.5 to 25 mg), which were given concurrently with bismuth, one patient developed a moderate anemia combined with poikilocytosis and anisocytosis.

The ratio of immediate reactions to the general number of injections was 9/1,501 or 1/167.4. The ratio of delayed reactions to the general number of injections given was 1/214.4. These data contain a higher percentage of untoward reactions than our previous investigation⁸ in cases of congenital syphilis, in which the respective ratios were 1/883 and 1/441. The higher frequency in immediate and delayed reactions in our

12 The baby died on June 7. Autopsy revealed lung abscess and hydrocephalus as causes of death. Examination of all viscera showed no evidence of damage due to medication. (Saccone Andrea. Personal communication to the authors.)

14 Local complications and pain after injection will be discussed elsewhere.

present series could be explained by the use of the intramuscular method of administration of mapharsen in many cases (pain may often be followed by nausea and vomiting) and by the increased dosage of mapharsen from 0.5 mg to 1 mg per kilogram of weight. Even these figures are lower than in our previous paper, which dealt chiefly with adult patients.¹⁵ In this group the respective ratios were 1/60.4 and 1/121. This proves that mapharsen is less toxic to children than to adults. Nine (0.06 per cent) immediate gastrointestinal reactions were observed in 1,507 injections. This incidence is small in comparison with that of the arsphenamines, following which there have been, according to various observers, from 7 to 25 per cent¹⁶ of mild reactions.

The lower index of toxicity of mapharsen is also illustrated by the following. Three of our cases suffered from severe gastrointestinal disturbances (vomiting, headache) after the injections of neoarsphenamine. These patients tolerated mapharsen well. No reactions developed. One patient had a generalized erythema, a scaly eruption following an injection of 0.2 Gm of arsphenamine. The patient received, one and one-half years later, a course of 14 mapharsen injections (dosage 5 to 35 mg) without any after-effects. On the other hand, only 1 patient sensitive to mapharsen (developed urticaria) tolerated neoarsphenamine well.

Blood Count Examinations.—Blood count studies were done in 48 cases. In most of the cases the blood count did not show any changes following mapharsen therapy. However, in 5 cases a decrease in the red blood cell count was noted (average decrease 620,000) as well as a lowering of the hemoglobin (average decrease 14 per cent) following 8.4 (average) of mapharsen injections. In 1 of these cases (G. H., aged 6 months) following 8 injections of mapharsen (average dosage 5.1 mg) the aforementioned changes in the red blood cell count and hemoglobin appeared together with poikilocytosis and anisocytosis. Three among these 5 patients were infants who tolerated the injections of mapharsen well and did not show any signs of discomfort or illness. The changes in the blood counts were discovered by routine repeated blood examinations. These changes in the blood counts were not of a grave character, however, they occurred in 3 of 10 cases of early congenital syphilis. And in our opinion that is quite a high percentage. This could be coincidental, but it could also quite possibly be explained by the high dosage of mapharsen given in the early cases (maximum dosage 1 mg per kilogram of weight).

Liver Function Tests.—Icterus indexes were performed in 32 cases. The majority of the tests were found to be normal. Following mapharsen therapy the icterus indexes were found to be elevated in 5 cases. In 3 of these cases (3 of 32, or 9.4 per cent) the icterus indexes were 10 to 12, in the other 2 (2 of 32, or 6.3 per cent) the indexes were 8 to 9.3. These percentages of 9.4 and 6.3 compare favorably with the figures on changes in the icterus indexes in one group of adults treated with mapharsen, in which the respective percentages were 19 and 19.¹⁷ This fact proves again that mapharsen is less toxic in children than in

adults. It is also noteworthy that 2 out of 3 patients with icterus indexes of 10 to 12 were children treated by the concurrent method of administration of mapharsen and bisnuth. In 2 cases the icterus indexes were found to be somewhat elevated (8.3-10) before mapharsen therapy was instituted. Mapharsen was then administered accompanied each time by an injection of liver extract.¹⁸ Following ten mapharsen injections and ten liver injections the icterus indexes in both cases became normal.¹⁷

Local Complications.¹⁸ (tables 5 and 6).—In a previous paper⁸ the fact was mentioned that the patients with early congenital syphilis¹⁹ who received the injections of mapharsen intramuscularly did not show any signs of general discomfort (fever or restlessness) or any local reaction (necrosis on the site of the injection). We may say that our present investigation confirmed these findings. We had the same experience with all our cases of early congenital syphilis with the exception of 1 case in which crying and restlessness occurred for the entire day following the injection of 8 mg of mapharsen. The patients with early congenital syphilis received altogether 138 intramuscular injections, and the maximum dosage administered was 15 mg.

TABLE 5—After-Effects of the Intramuscular Administration of Mapharsen in Adults

Total number of patients treated	10
Total number of injections given	233
Number of injections which were followed by very mild soreness (duration $\frac{1}{2}$ hour)	179
Number of injections which were followed by slight or moderate pains (duration 1-6 hours)	54
Number of injections which were followed by severe pain (duration 6-24 hours)	46
Number of injections which were followed by long lasting severe pains (duration 2-10 days)	6

Since it is very difficult to evaluate the kind and amount of pain in infants, we decided to use the intramuscular method for children old enough to be interrogated about the after-effects. Nineteen children from 3 to 12 years of age with late congenital syphilis were treated. The maximum dosage in many of these cases was as high as 20 mg; 357 injections were given. The information about the pain was obtained from the children, the parents or the ward nurse in charge.²⁰

All children, with the exception of those who had special complaints, stated that the injection of mapharsen was followed by a mild soreness lasting from a quarter of an hour to one hour. Special complaints were recorded by 9 patients after 60 injections. Forty-five of these complaints were of slight or moderate pain lasting from one to four hours. These pains did not interfere with the children's usual activities, such as playing and walking. Fifteen other complaints were of severe pain sometimes lasting almost an entire day. In 1 case the pain, after an injection of 2 mg, lasted all night and was accompanied with vomiting. The patient also vomited the entire week following an injection of 4 mg of mapharsen. The same patient later received 5 more injections of mapharsen (dosage 4 to 12 mg).

18 Mapharsen was dissolved in isotonic solution of sodium chloride 60 mg to 10 cc of solution (Sharp E. Personal communication to the authors). Later a more concentrated solution was used (60 mg of mapharsen to 5 cc of saline solution). For the last three months plain distilled water has also been used as a solvent. Our impression is that the concentration of mapharsen and the kind of solvent used have little if any influence on the amount and kind of complications.

19 The use of mapharsen in early congenital syphilis was suggested by Dr. Rosen (cited by Astrachan¹²).

without any special complaints. In another case the pain lasted for about twenty-four hours several times and the intramuscular method of administration of mapharsen in this case was abandoned.

The Intramuscular Use of Mapharsen for Adult Patients (table 5).—Children are prone to forget pain on its cessation, they may even discount it or overlook it in the heat of an interesting or competitive game. It is questionable, therefore, whether the answers given by children can be used for evaluation of the kind and degree of after-effects following the intramuscular administration of any medication. It is for this reason that we decided to include in this investigation information about local complications following the intramuscular use of mapharsen to adult patients. They were selected mostly from among obese women in whom intravenous therapy was impossible because of bad veins. Nineteen cases were observed and 235 injections were given. The maximum dosage administered was 30 mg. and the number of injections given varied from 1 to 36. The initial dosage was 4 mg. It was increased weekly by 2 mg. until 30 mg. was reached. The very gradual and slow increase in the dosage can easily be understood if it will be remembered that in experiments of this kind one must proceed with caution because of the possibility of serious complications.

The patients were interrogated each time as to the presence or absence of any reactions, the kind and degree of pain, if any, following the injections of mapharsen. As with the children all patients, with the exception of those who had special complaints, stated that the injection of mapharsen was followed by a mild soreness lasting from a quarter of an hour to one hour. Special complaints were recorded after 106 injections were given to 17 patients, 54 of these complaints were of slight or moderate pain lasting generally from one to six hours. One patient complained once of a sensation which felt as if "some one was drilling the bone," and the pain lasted all day. The same patient, however, stated that she had no pain at all after the succeeding injection of mapharsen. One patient complained of a slight pain lasting for two days, another of the same group stated that the pain was less pronounced than that experienced after bismarsen injections. Prior to the institution of mapharsen therapy 1 patient was treated with intramuscular injections of sulfur arsphenamine (0.1 to 0.2 Gm.). She stated that after each injection she suffered a severe burning sensation which lasted for several hours, while the injections of mapharsen did not cause any after-effects. The other fifty-two special complaints were of pains which could be classified as severe. These lasted in the average for six to twenty-four hours and even longer. These pains were characterized as "shooting" or "sharp" or the patient complained of inability to walk or severe pain in the leg causing incapacitation for three days. Three patients complained of pain lasting about a week. One complained of pain lasting ten days. It is interesting to note that some of these patients, after complaining of severe pain several times, stated that the pain was very slight at the next visit, even though the dosage of mapharsen was the same or even larger.

COMMENT

This investigation confirmed our conclusions in previous investigations that mapharsen is a useful drug in the treatment of cases of late congenital syphilis.²¹ In

55.5 per cent of our cases the blood serologic reaction reversed partially or completely. This percentage is a fairly good one in cases of late congenital syphilis, in which in not less than 50 per cent of instances there is a fixed serologic reaction, regardless of treatment given.²² The fact that improvement occurred in all 6 cases of interstitial keratitis following mapharsen therapy emphasizes its value in cases of late congenital syphilis.

In a previous contribution a preference was expressed for the concurrent method of administration of bismuth compounds and mapharsen when dealing with cases of late congenital syphilis.¹⁴ With regard to this problem an analysis of the serologic response in our cases showed that there were more improved cases (58.8 per cent) among those treated with the concurrent method than among those treated with the alternate method (53.5 per cent). The concurrent method was used more among the improved cases (40 per cent) than among the unimproved ones (35 per cent). Although the difference in percentages is a very small one, it still points to a favorable influence of the concurrent method on the effectiveness of mapharsen therapy. (The influence of the slightly higher number of injections of mapharsen given in the concurrent group over that given in the alternate group may be discounted because the average number of bismuth injections given in the alternate group was larger than that given in the concurrent group.)

Four of our cases showed an improvement only when the concurrent method was used; this also points to the advisability of the use of this method. On the other hand we have to admit that the concurrent method is more liable to cause untoward reactions than the alternate one (case A. H., Grundice). For this reason the concurrent method should be used only for healthy patients and it should be combined with the alternate method of administration, that is, a course of bismuth and mapharsen given concurrently should be followed by courses of bismuth and mapharsen given alternately. It is also imperative that the patients be carefully observed and frequent blood counts and liver function tests be done.

In 7 out of 10 cases of early congenital syphilis the serologic reaction reversed partly or completely after an average of 17.3 injections of mapharsen were administered. A positive spinal fluid in a 4 months old baby reversed to negative after 3 bismuth and 12 mapharsen injections were administered. These data confirm our opinion in our previous investigation⁸ that mapharsen may be useful in cases of early congenital syphilis. Further observation of the efficacy of this drug in many more cases will be necessary before we can come to a definite conclusion.

Because of the large number (3 out of 10 cases) of early congenital syphilis in which regressive changes in the blood count could be attributed to mapharsen therapy, we feel that the maximum dosage employed by us (1 mg. per kilogram of weight) was probably too high for infants, who are usually in a weakened condition as the result of their lowered resistance, malnutrition and toxemia, which are caused by the spirochetosis. On the other hand, the maximum dosage employed in our previous investigation⁸ (0.5 mg. per kilogram of weight) did not cause any after-effects.

²² Cole, H. N., Usilton, Lida J., Moore, J. E., O'Leary, P. A., Stokes, J. H., Wile, U. J., Parrin, Thomas Jr. and Vonderlehr, R. A. Late Prenatal Syphilis with Special Reference to Interstitial Keratitis. Its Prevention and Treatment. Arch. Dermat. & Syph. 35: 563 (April) 1937. Moore.¹⁶

We feel therefore, that 0.75 mg per kilogram of weight would be the optimum dosage for cases of early congenital syphilis.

The maximum dosage of mapharsen in some of our cases of late congenital syphilis was somewhat higher than in the first investigation⁵ (0.75 to 1 mg instead of 0.5 mg per kilogram of weight). In view of the relative increase in the ratio of reactions in this series, we believe that 0.75 mg per kilogram of weight would probably be the most suitable dosage in cases of late congenital syphilis.

As to the question of the lower toxicity of mapharsen in comparison with other arsenicals we stress the absence of exfoliative dermatitis, nitritoid reactions, the small number of immediate and delayed reactions in our series and the fact that several of our patients who were sensitive to neoarsphenamine tolerated mapharsen well. The lower ratios of reactions in our series in comparison with those in a previous paper¹² which dealt chiefly with adult patients proves again that mapharsen is less toxic in children than in adults. This is also confirmed by the very small percentage of increased icterus indexes in comparison with that of the adult group.¹⁷

It is also noteworthy that all 6 pregnant women tolerated mapharsen well and developed no untoward reactions except 1 case of nausea (once) and 1 of pruritus. This seems to confirm the opinion of one of us about the low toxicity of mapharsen in cases of syphilis and pregnancy.²³

Where the question of the feasibility of intramuscular administration of mapharsen is concerned, we stress the facts that, while some patients complained of severe and long lasting pain, the majority of the injections (in adults) were followed by slight or moderate pain only, that not a single case of local necrosis developed following 730 intramuscular injections of mapharsen (in adults and children) and that serious systemic complications did not appear as a result of this method of administration.

It is also noteworthy that 2 patients who received sulfarsphenamine or bismarsen therapy prior to mapharsen injections stated that the intramuscular injections of mapharsen caused less pain and discomfort than the two aforementioned drugs. Taking all this into consideration, we feel justified in stating that in selected cases the intramuscular method of administration of mapharsen may be tried. It should be employed, however, very cautiously, the dosages increased very slowly, and only those cases treated in which all attempts at intravenous therapy have failed.

CONCLUSIONS

1 Mapharsen is a good drug for patients with late congenital syphilis.

2 It is useful in cases of interstitial keratitis.

3 The concurrent method of administration of bismuth compounds and mapharsen in late congenital syphilis should be used for healthy patients only and should be combined with the alternate method of administration. Frequent blood counts and liver function tests should be performed on these patients.

4 Mapharsen proved to be useful in our cases of early congenital syphilis.

5 Further observation of many more cases will be necessary in order to come to a definite conclusion about the efficacy of mapharsen in early congenital syphilis.

6 We believe that 0.75 mg per kilogram of weight should be the maximum dosage for patients with any form of congenital syphilis.

7 Mapharsen is less toxic to children than to adults.

8 Mapharsen can be given intramuscularly in selected cases, however, it should be used only in cases in which all attempts at intravenous therapy have failed.

9 Further experimentation with various solvents is desirable in order to find the least painful method of intramuscular administration of mapharsen.

ABSTRACT OF DISCUSSION

DR NORMAN R. INGRAHAM JR., Philadelphia. Many of the studies of a few years ago having to do with the treatment of congenital syphilis (particularly of early congenital syphilis) have had their present scientific value greatly diminished because of a lack of appreciation of the conditions affecting the interpretation of the blood serologic test for syphilis in infancy, because of the roentgenogram in the first few months of life or through a failure on the part of the various authors to make clear the diagnostic standards employed. Moreover the inability to keep these patients under treatment observation with sufficient regularity for a long enough period of time to make available mass statistics has rendered information concerning the long time results of treatment of congenital syphilis hard to obtain. Information such as has been presented could be rendered even more valuable by the addition of brief statements concerning (1) the diagnostic criteria employed, (2) the dosage interval and the regularity of administration of treatment and (3) the total duration of observation. These suggestions would apply to the medical follow-up of the apparently normal infant offspring of the six syphilitic mothers included in the study as well as to the proved cases of congenital syphilis. I have had no personal experience with the use of intramuscular mapharsen in the treatment of congenital syphilis. The intramuscular arsenicals which I have used routinely for infants over a period of years, namely sulfarsphenamine at the Philadelphia General Hospital and bismarsen at the University Hospital, have been therapeutically effective and have resulted in no serious problems from the standpoint of either local or systemic reaction. In the dosage that is used for small infants, even neoarsphenamine may be given intramuscularly (or under the fascia of the scalp). Intramuscular arsenical therapy has definite indications in the treatment of infantile congenital syphilis and in some stages of adult syphilis. I feel, therefore, that this evidence of the possible value of intramuscular mapharsen in the treatment of congenital syphilis is particularly timely.

DR JOHN E. RAUSCHKOLB, Cleveland. In general my observations agree with those of the authors—that is, mapharsen is not only a good but an excellent drug in the treatment of congenital syphilis, especially the early types, for it is in this stage that the arsenicals are of the most value in preventing the destructive changes. The dosage I use is even more conservative—it being 0.5 mg per kilogram of body weight as a maximum. Mapharsen can be given intramuscularly with safety. Especially is this true in the early congenital types. The drug should be given in concentrations of 10 per cent strength in order to keep down the volume, thus minimizing inflammatory areas at the site of the injection. Needless to say, these injections should be given in the upper outer quadrant of the buttocks and intramuscularly, otherwise abscess may follow. I have had one abscess develop, in which concurrent therapy was administered, consisting of both mapharsen and bismuth salicylate injections. Of course, this complication may have been produced by bismuth or a combination of bismuth and mapharsen. In my experience solvents play but a minor factor in preventing pain, but the solvent may raise the incidence of toxic reaction. I now am using only distilled water in concentrations of 5 to 10 per cent. I cannot agree with the authors as to its usefulness in interstitial keratitis. In my experience mapharsen had no beneficial results on this late acute congenital manifestation. Perhaps their improvement may be the combined effect

²³ Astrachan, G. D. Syphilis in Pregnancy, New York State J. Med. 40: 43 (Jan. 1) 1940.

of foreign protein reaction produced by the drug given intramuscularly plus the drug action

DR GIRSCH D ASTRACHAN, New York Follow-up of cases is important this was attempted by the social service department and in some cases useful information was obtained, but there are difficulties The proper procedure in intramuscular therapy is for the injections to be administered by one individual all the time All the intramuscular injections given in the Metropolitan Hospital Dispensary were administered by one man only (Dr Israel Hirshon) In our previous investigation the dosage used was 0.5 mg per kilogram of body weight This dosage was found somewhat ineffective and we decided to increase it We now feel that 0.75 mg per kilogram of body weight would be the proper dosage The concurrent method was avoided in most of the cases of early congenital syphilis because of the increased dosage of mapharsen employed and also because we felt that infants who are usually in a weakened condition as a result of their lowered resistance, malnutrition and toxemia may develop reactions if the concurrent method is used These patients were treated continuously by alternate courses of bismuth and mapharsen Among our cases were 3 of an acute form of interstitial keratitis and all these responded well to mapharsen therapy

Clinical Notes, Suggestions and New Instruments

A DEVICE FOR DETECTING SIMULATED UNILATERAL DEAFNESS

MAJOR LOUIS K. PITMAN
MEDICAL CORPS ARMY OF THE UNITED STATES

Simulated unilateral deafness is sometimes practiced in wartime among draftees in order to avoid military conscription and among soldiers to avoid duty or to claim compensation after military discharge

Most cases of suspected simulated deafness are unilateral This is due to the fact that a double deafness would previ-

Fig 1—Left Words spoken into bell A will be conveyed into suspect's right ear only and the noise from the Barany apparatus will enter the left ear Right The procedure is reversed Now the spoken words enter the suspect's left ear and the noise his right ear

ously have attracted attention whereas a onesided deafness might have existed without being detected Also it is easier to simulate onesided deafness

Released for publication by the War Department Manuscript Board which assumes no responsibility other than censorship for the contents of this article

Major Pitman is chief of the Ear Nose and Throat Service Station Hospital Basic Training Center 7 Army Air Force Technical Training Command Atlantic City N J

The examiner must keep in mind that many of these persons have given considerable study to the malingering tests and have developed shrewd technics in carrying out their attempts to deceive After some practice the malingerer has learned to ignore sounds, tones and words directed toward the ear in which he is simulating deafness He also learns when to elevate the pitch of his voice during the examination

The tests now in use, while attaining a certain degree of success, are not foolproof The tests widely used are

1 Stethoscope Test

—A common stethoscope having one tube closed with a wooden plug is adjusted to the patient's ears the open tube to the suspected ear and the closed one to the normal ear The examiner speaks into the bell of the stethoscope having the patient repeat what he hears The stethoscope is then removed, the normal ear is tightly closed and the same formula is repeated to the patient He will say he cannot hear, whereas he has already repeated after the examiner with the normal ear tightly closed with the plugged arm of the stethoscope

This test is frequently unsuccessful if the malingerer has learned to ignore all sounds going to the suspected ear

2 *Lombard's Test*—The patient reads some selected passage aloud As long as he hears his own voice it does not change in pitch or articulation The Barany noise apparatus is then applied to the sound ear while he continues reading If he is actually deaf in the other ear his voice will become elevated in pitch and his articulation blurred If he hears with that ear his voice will remain unaffected

This test can also fail in its purpose if the patient learns to elevate his voice when the noise apparatus is directed to his normal ear

3 *Double Conversation Test*—This test is done by two examiners Simultaneously each examiner tries to hold a conversation with the suspect through a tube leading to each ear In unilateral deafness the suspect will ignore the conversation directed to the affected ear However a good malingerer with a little practice can learn to ignore the conversation directed toward the ear in which he is simulating deafness

All other tests for unilateral deafness are variations of the same principles

MODE OF OPERATION OF AUTHOR'S TEST

The device described in this paper makes use of these tests in a new way By interfering with the malingerer's powers of concentration it renders him helpless to carry out his purpose

A common stethoscope is adjusted to the suspect's ears with the bell behind his back At the fork of the stethoscope is set a two in one petcock (fig 1) fitted with tubes A and B The stethoscope bell is attached to the far end of tube A, the Barany noise apparatus to the far end of tube B When the handle of the petcock (fig 1 left) is moved clockwise until blocked words spoken into the bell will be conveyed to the suspect's right ear only and the noise from the Barany apparatus will enter his left ear The procedure is then immediately reversed by moving handle H counterclockwise (fig 1, right) Now the spoken words enter the suspect's left ear, and the noise his right ear The result is that the subject is bewildered, as shown by his responses to the standard tests

Fig 2—The inner workings of the two in one petcock

1 *Stethoscope Test*—In true unilateral deafness, the normal ear will perceive the spoken voice or alternating noise, and the subject will respond promptly. The malingerer hears the noise and the spoken voice simultaneously, but cannot tell to which ear each is directed. A turn of the handle, interchanging the direction of the spoken voice and noise, will increase his indecision. He will not be able to respond properly.

2 *Lombard's Test*—In true unilateral deafness the patient reading aloud will automatically raise his voice when noise is directed to the normal ear and lower it when the noise is switched to the other ear. But the rapid shift of the noise from one ear to the other by my instrument confuses the malingerer. He will not be able to synchronize his tone with the rise and fall of the noise.

3 *Double Conversation Test*—The Bruny noise apparatus is replaced by a second stethoscope bell. Simultaneous conversations carried on by two examiners will not confuse a genuine unilateral deaf person, for he can perceive only one voice. The malingerer, however, will hear both voices and their rapid changing from one ear to the other will greatly confuse him and prevent him from making proper responses.

RESULTS OF TESTS

This device has been put to actual use at the Station Hospital, where it was developed by the author, while Lieut. Col. Carl A. Schuck was commanding officer. It has been found to be very valuable in detecting simulated unilateral deafness. Even if the malingerer knows of the tests he cannot protect himself against them, he gives himself away. The device therefore seems to offer a foolproof application of the accepted means of examining this type of case.

A SIMPLE HOLDER FOR THE ADMINISTRATION OF PENTOTHAL SODIUM

CAPTAIN ROBERT B. HOPE
MEDICAL CORPS ARMY OF THE UNITED STATES

Intravenous anesthesia has reached an established place in the armamentarium of the civilian anesthetist. It is now coming to the foreground more and more in the practice of military medicine. It is adaptable in selected cases to surgery both in the field and in the hospital. The anesthetic of choice is pentothal sodium. When judiciously used by a trained anesthetist, anesthetic complications are very few.

Fig 1—Holder for administration of pentothal sodium. A thumb catch which holds 50 cc syringe in cradle.

Pentothal sodium is best given in a 2.5 per cent solution. Dilution to this strength necessitates using a large syringe. It is important that during the administration of pentothal sodium

a free airway be maintained at all times, which is accomplished by continuously holding up the patient's jaw. To do this, hold a needle attached to a large syringe in place. It is impossible for the anesthetist to administer the anesthetic as well as oxygen if necessary, unless he has an assistant. This has been obviated by the development of a mechanical holder for the

Fig 2—Apparatus in use in operation: open reduction of clavicle.

pentothal syringe. These are made somewhat on the principle of the mechanical stage, so that the anesthetist can merely turn a thumb screw and administer the anesthetic. There are several models manufactured; they are relatively expensive and sometimes not readily obtainable, especially overseas. Not one was available to me.

I presented the problem to our utilities department. The principle and the general needs the instrument must meet were described. For the mechanical part, to push the plunger home a $4\frac{1}{2}$ inch long, $\frac{1}{4}$ inch diameter bolt and nut were used. The instrument was made to accommodate a 30 cc syringe, since we had more of that size on hand than the 50 cc size. The latter size would probably be preferable.

The instrument depicted in figure 1 was the result. It is simple, entirely dependable and satisfactory in operation. The cost of making is but a few hours' time. The materials can be found in any utilities department: a bolt and nut, some light weight sheet metal, some inner tube rubber, a cap from a metal cot post and some screws. It is an example of the ingenuity and resourcefulness that we continually find in the utilities departments of our various units. We feel that we are particularly fortunate to have such personnel in our organization.

USE OF THE INSTRUMENT

The setup is very simple. A 30 cc syringe will accommodate the 40 cc of solution that is necessary in diluting 1 Gm of pentothal to make a 2.5 per cent solution. The full syringe is placed in the holder. A latex rubber tube 20 cm in length with a ground glass adapter and 20 gage needle is attached to the syringe. The pentothal solution is then forced out to the needle, and the tube is filled by pushing the plunger home. This brings the solution to about the 30 cc mark in the syringe. The needle is inserted in the vein in the usual manner. Pentothal can then be administered at will by merely turning the thumb screw.

In surgery a number of syringes, needles and units of rubber tubing with adapters are kept in separate sterile packs. With ordinary sterile technic, by merely changing the tubing unit and needle, pentothal sodium solution left in the syringe is still sterile and usable for another case. Thus several short cases to be done in succession can be handled on one syringe. If more pentothal is needed for the same case the solution is mixed up in a new syringe and attached to the tubing and needle, which is still inserted in the vein.

The examiner must keep in mind that many of these persons have given considerable study to the malingering tests and have developed shrewd technics in carrying out their attempts to deceive After some practice the malingerer has learned to ignore sounds, tones and words directed toward the ear in which he is simulating deafness He also learns when to elevate the pitch of his voice during the examination

The tests now in use, while attaining a certain degree of success are not foolproof The tests widely used are

1 Stethoscope Test

—A common stethoscope having one tube closed with a wooden plug is adjusted to the patient's ears the open tube to the suspected ear and the closed one to the normal ear The examiner speaks into the bell of the stethoscope having the patient repeat what he hears The stethoscope is then removed, the normal ear is tightly closed and the same formula is repeated to the patient He will say he cannot hear, whereas he has already repeated after the examiner with the normal ear tightly closed with the plugged arm of the stethoscope

Fig 2—The inner workings of the two in one petcock

This test is frequently unsuccessful if the malingerer has learned to ignore all sounds going to the suspected ear

2 Lombard's Test—The patient reads some selected passage aloud As long as he hears his own voice it does not change in pitch or articulation The Barany noise apparatus is then applied to the sound ear while he continues reading If he is actually deaf in the other ear his voice will become elevated in pitch and his articulation blurred If he hears with that ear his voice will remain unaffected

This test can also fail in its purpose if the patient learns to elevate his voice when the noise apparatus is directed to his normal ear

3 Double Conversation Test—This test is done by two examiners Simultaneously each examiner tries to hold a conversation with the suspect through a tube leading to each ear In unilateral deafness the suspect will ignore the conversation directed to the affected ear However a good malingerer with a little practice can learn to ignore the conversation directed toward the ear in which he is simulating deafness

All other tests for unilateral deafness are variations of the same principles

MODE OF OPERATION OF AUTHOR'S TEST

The device described in this paper makes use of these tests in a new way By interfering with the malingerer's powers of concentration it renders him helpless to carry out his purpose

A common stethoscope is adjusted to the suspect's ears with the bell behind his back At the fork of the stethoscope is set a two in one petcock (fig 1) fitted with tubes A and B The stethoscope bell is attached to the far end of tube A the Barany noise apparatus to the far end of tube B When the handle of the petcock (fig 1 left) is moved clockwise until blocked words spoken into the bell will be conveyed to the suspect's right ear only and the noise from the Barany apparatus will enter his left ear The procedure is then immediately reversed by moving handle H counterclockwise (fig 1, right) Now the spoken words enter the suspect's left ear, and the noise his right ear The result is that the subject is bewildered, as shown by his responses to the standard tests

1 *Stethoscope Test*—In true unilateral deafness, the normal ear will perceive the spoken voice or alternating noise, and the subject will respond promptly. The malingering hears the noise and the spoken voice simultaneously but cannot tell to which ear each is directed. A turn of the handle, interchanging the direction of the spoken voice and noise, will increase his indecision. He will not be able to respond properly.

2 *Lombard's Test*—In true unilateral deafness the patient reading aloud will automatically raise his voice when noise is directed to the normal ear and lower it when the noise is switched to the other ear. But the rapid shift of the noise from one ear to the other by my instrument confuses the malingering. He will not be able to synchronize his tone with the rise and fall of the noise.

3 *Double Conversation Test*—The Brany noise apparatus is replaced by a second stethoscope bell. Simultaneous conversations carried on by two examiners will not confuse a genuine unilateral deaf person, for he can perceive only one voice. The malingering, however, will hear both voices, and their rapid changing from one ear to the other will greatly confuse him and prevent him from making proper responses.

RESULTS OF TESTS

This device has been put to actual use at the Station Hospital, where it was developed by the author while Lieut. Col. Carl A. Schuck was commanding officer. It has been found to be very valuable in detecting simulated unilateral deafness. Even if the malingering knows of the tests he cannot protect himself against them; he gives himself away. The device therefore seems to offer a foolproof application of the accepted means of examining this type of case.

A SIMPLE HOLDER FOR THE ADMINISTRATION OF PENTOTHAL SODIUM

CAPTAIN ROBERT B. HOPE
MEDICAL CORPS ARMY OF THE UNITED STATES

Intravenous anesthesia has reached an established place in the armamentarium of the civilian anesthetist. It is now coming to the foreground more and more in the practice of military medicine. It is adaptable in selected cases to surgery both in the field and in the hospital. The anesthetic of choice is pentothal sodium. When judiciously used by a trained anesthetist, anesthetic complications are very few.

Fig 1—Holder for administration of pentothal sodium. A thumb catch which holds 50 cc syringe in cradle.

Pentothal sodium is best given in a 2.5 per cent solution. Dilution to this strength necessitates using a large syringe. It is important that during the administration of pentothal sodium

a free airway be maintained at all times, which is accomplished by continuously holding up the patient's jaw. To do this hold a needle attached to a large syringe in place. It is impossible for the anesthetist to administer the anesthetic as well as oxygen if necessary, unless he has an assistant. This has been obviated by the development of a mechanical holder for the

Fig 2—Apparatus in use in operation open reduction of clavicle.

pentothal syringe. These are made somewhat on the principle of the mechanical stage, so that the anesthetist can merely turn a thumb screw and administer the anesthetic. There are several models manufactured; they are relatively expensive and sometimes not readily obtainable, especially overseas. Not one was available to me.

I presented the problem to our utilities department. The principle and the general needs the instrument must meet were described. For the mechanical part, to push the plunger home a $4\frac{1}{2}$ inch long $\frac{1}{4}$ inch diameter bolt and nut were used. The instrument was made to accommodate a 30 cc syringe, since we had more of that size on hand than the 50 cc size. The latter size would probably be preferable.

The instrument depicted in figure 1 was the result. It is simple, entirely dependable and satisfactory in operation. The cost of making is but a few hours' time. The materials can be found in any utilities department: a bolt and nut, some light weight sheet metal, some inner tube rubber, a cap from a metal cot post and some screws. It is an example of the ingenuity and resourcefulness that we continually find in the utilities departments of our various units. We feel that we are particularly fortunate to have such personnel in our organization.

USE OF THE INSTRUMENT

The setup is very simple. A 30 cc syringe will accommodate the 40 cc of solution that is necessary in diluting 1 Gm of pentothal to make a 2.5 per cent solution. The full syringe is placed in the holder. A latex rubber tube 20 cm in length with a ground glass adapter and 20 gage needle is attached to the syringe. The pentothal solution is then forced out to the needle, and the tube is filled by pushing the plunger home. This brings the solution to about the 30 cc mark in the syringe. The needle is inserted in the vein in the usual manner. Pentothal can then be administered at will by merely turning the thumb screw.

In surgery a number of syringes, needles and units of rubber tubing with adapters are kept in separate sterile packs. With ordinary sterile technique, by merely changing the tubing unit and needle, pentothal sodium solution left in the syringe is still sterile and usable for another case. Thus several short cases to be done in succession can be handled on one syringe. If more pentothal is needed for the same case the solution is mixed up in a new syringe and attached to the tubing and needle, which is still inserted in the vein.

SEVERE RENAL IRRITATION RESULTING FROM
FOREIGN PROTEIN (TYPHOID) FEVER
THERAPYR. D. TAYLOR, M.D. AND IRVINE H. PAGE, M.D.
INDIANAPOLIS

We have recently studied 2 patients with renal disease in whom signs of severe renal irritation developed following fever induced by intravenous typhoid vaccine. Engman and McGarry¹ briefly describe a patient who developed microscopic hematuria after receiving intravenous typhoid vaccine and Campbell² reported hematuria in an arthritic patient being treated with "nonspecific" protein (typhoid) fever therapy. In 1932 Hench³ reviewed the usual and unusual reactions of typhoid vaccine protein therapy in a series of 2,500 patients. There were 14 unusual reactions in this series, 2 of whom died with anuria. At necropsy acute diffuse nephritis was found in 1 case and no renal lesion in the other. Our 2 patients had previous renal disease—the nephrotic stage of hemorrhagic Bright's disease in 1, and malignant hypertension in the other—conditions which might be contraindications to foreign protein therapy.⁴

Because pyrexia induced by injection of foreign protein has been suggested in the treatment of various types of vascular diseases, including hypertension, it has seemed to us well to point out by these 2 examples that it is a therapy not without danger especially in those with preexisting renal damage.

Course of laboratory examinations of patient 1 while under treatment

REPORT OF CASES

CASE 1—A Negro woman aged 35 admitted to the Lilly Clinic complained of hypertension of two years duration, headache, nausea and vomiting. She was bedridden for two months before admission. The arterial blood pressure was 240 systolic and 140 diastolic. Grade 4 constriction and sclerosis of the retinal arterioles, grade 1 retinal exudates, grade 2 retinal hemorrhages and grade 1 papilledema led to the diagnosis of malignant hypertension. Urea clearance was 47 per cent of the average normal. The maximal ability to concentrate urine was 1020. There were 900,000 red blood cells in the twelve hour specimen of urine. The patient excreted about 1 Gm of protein daily. The electrocardiogram showed left axis deviation.

She was treated for fourteen months with antipressor renal extracts which resulted in lowering the arterial blood pressure to an average of 200 systolic, 110 diastolic and regression of retinopathy with disappearance of hemorrhages, exudates and

papilledema. During these fourteen months she had hematuria varying from normal to 5,500,000 red blood cells in twelve hours.

On May 21, 1942 it was decided to determine whether or not fever induced with typhoid vaccine could mimic the results of antipressor renal extracts. She was given an intravenous infusion of 100 cc of isotonic solution of sodium chloride that contained 0.20 cc of typhoid mixed vaccine according to the method of Solomon and Somkin.⁵ After a violent chill, the temperature and pulse rate rose to 104 F and 140 respectively and the respirations to 37. The following day gross hematuria was noted, but despite this a similar dose of mixed vaccine was given, again followed by a chill and a rise in temperature to 103.4 F. The gross hematuria persisted for ten days. There was no oliguria, edema or increase in arterial pressure. Urea clearance fell to 3 per cent of average normal. Nausea and vomiting developed and persisted for six weeks. During this time nonprotein nitrogen ranged between 100 and 207 mg per hundred cubic centimeters, hemorrhages and exudates reappeared in the ocular fundi and the hemoglobin level fell to 37 per cent of normal. On July 27 urea clearance had risen to 7 per cent of average normal. The Addison count of the urinary sediment showed 750,000 red blood cells in twelve hours, the maximum ability to concentrate urine was 1012, and the hemoglobin level had risen to 43 per cent of average normal. Nausea and vomiting no longer occurred. The prognosis is grave and it is doubtful that she will return to her former state of health.

CASE 2—A white boy aged 2½ years was admitted to the Indianapolis City Hospital on May 19, 1938. Six weeks before admission the child had a rash followed in three weeks by swelling of his eyes, and still later by anasarca. The mother reported oliguria and increasing irritability. The physical findings on admission were temperature 99.4 F, arterial blood pressure 114 systolic and 70 diastolic, there were generalized edema, ascites and moist rales over the base of the left lung. The urine contained 15 per cent albumin, 10 to 20 hyaline casts per high power field, a few pus cells and occasional red cells. Urea clearance was 100 per cent of average normal. The red blood cell count was 4.10 millions, the white blood cell count 6,500 and the hemoglobin level 61.4 per cent of normal. Total plasma proteins were 4.7 Gm per hundred cubic centimeters, albumin was 0.6 Gm

per hundred cubic centimeters. A diagnosis of the nephrotic stage of hemorrhagic Bright's disease was made. He was in the hospital six months, during which time treatment consisted of bed rest, a salt free, low sodium diet, a high protein, high vitamin diet, intravenous acacia, and potassium citrate and mercurial diuretics. This management maintained edema in the grade 1 stage for the first three hospital months. At the end of the fourth month edema again became grade 4 and blood pressure rose to an average of 138 systolic and 100 diastolic. At this time it was decided to use triple typhoid vaccine in an effort to increase renal blood flow, thereby hastening recovery. On September 20, four months after admission, he was given 0.4 cc of typhoid H vaccine intramuscularly. Two days later he received 0.6 cc, neither of which produced a rise in temperature. Two weeks later 0.1 cc and 0.2 cc of typhoid H vaccine intravenously produced no fever. Three weeks later 0.25 cc of vaccine intravenously produced a temperature rise to 101 F. On October 18 0.3 cc of typhoid vaccine was given intravenously. Three days later 0.5 cc was injected intravenously. The maximum temperature rise was to 100 F. On the following day he was given 0.2 cc of triple typhoid vaccine intravenously. The temperature rose to 101 F. Three days later urea clearance fell to 28 per cent of normal and gross hematuria appeared. Urinary protein increased from an average of 2.5 Gm in twenty-four hours to 6 Gm in twenty-four hours. Hematuria

5 Solomon, H. A. and Somkin, Eugene. An Improved Method of Obtaining Sustained Controlled Hyperpyrexia with Triple Typhoid Vaccine. *Am. J. M. Sc.* 203: 736 (May) 1942.

persisted between 750,000 and 2,500,000 red blood cells in twelve hours, and urea clearance was depressed below 60 per cent of average normal for three months. At no time was there oliguria, increase of edema or rise in arterial blood pressure. At the end of this time hematuria disappeared and urea clearance returned to normal. The child subsequently recovered from nephritis as evidenced by absence of edema and proteinuria, normal ability to concentrate urine (1 027) and a normal urinary sediment count on May 28, 1942.

COMMENT

Intravenously injected typhoid vaccine was used for these 2 patients in the hope that in the one suffering from malignant hypertension the fever induced would lower arterial pressure and in the other, with the nephrotic syndrome, that edema would disappear. Whatever therapeutic effect occurred was obscured by the appearance of signs of severe renal damage. The nature of the damage is not known, but that it was severe is indicated by diminution of urea clearance, azotemia and hematuria.

Typhoid vaccine has been widely used to induce fever in a variety of diseases and especially in arthritis and peripheral vascular disease. In most cases of this type renal disease is not present. Our experience suggests that preexisting renal disease should warn the clinician of the possible danger of this type of therapy.

CONCLUSIONS

Fever induced by intravenous injection of typhoid vaccine caused evidence of severe renal irritation in a patient suffering from malignant hypertension and in a patient in the nephrotic stage of hemorrhagic Bright's disease. It appears that patients with renal disease should be treated by this method with great caution if at all.

Special Article

STANDARDS OF EFFECTIVE ADMINISTRATION OF INHALATIONAL THERAPY

BY THE COMMITTEE ON PUBLIC HEALTH RELATIONS
OF THE NEW YORK ACADEMY OF MEDICINE

The importance of inhalational therapy in modern medical practice is shown by its use in cardiac failure, coronary artery disease, asthma, atelectasis of the lungs of the newborn, postoperative atelectasis, pneumonia, pulmonary edema, emphysema and cerebral thrombosis. A proper understanding of the technic is especially necessary at this time because of its value in the treatment of war gas poisoning, severe hemorrhage, acute altitude sickness, and shock.

The therapeutic use of oxygen is based on the existence of a state of anoxia or of tissue oxygen want. This may be produced by failure of an adequate pressure of oxygen to reach the pulmonary capillaries or by a lowered blood flow which is responsible for a disproportionately large amount of oxygen being taken out of the capillaries, resulting in a diminished oxygen pressure insufficient for normal function of the tissues. Oxygen want may, however, take place with a normal arterial saturation as in a thrombosis of the coronary, popliteal or cerebral artery. Treatment under these circumstances makes use of the increased pressure of oxygen physically dissolved in the blood which is of special value not only in increasing the tension of oxygen through an artery that still may be partly

patent but, more significantly, by increasing the tension in the collateral circulation which feeds the area of the obstructed artery. The most manifest signs of the physiologic advantages of inhalation of oxygen are diminution in pulse rate, cyanosis, dyspnea, restlessness and delirium, and the decrease in the volume of pulmonary ventilation.

Although administration of oxygen is the mainstay of this therapy, new procedures have been developed to maintain respiratory function. These include the administration of helium and of oxygen or helium-oxygen mixtures under positive pressure. The usefulness of substituting helium for nitrogen in a respirable gas mixture is due to the lower specific gravity of helium which makes it possible to breathe through constricted pulmonary passageways at almost one half the effort required for respiration of air or of pure oxygen. The decreased physical pressure necessary for the inhalation of a helium-oxygen mixture results in a lowering of the elevated negative pressure within the chest that occurs in obstructive dyspnea. Positive pressure provided in inspiration tends to prevent the excessive negative intrapulmonary pressure from exerting a suction action on the intrathoracic bronchi and pulmonary epithelium and thus is apt to inhibit the formation of mucus from the bronchi and edema from the pulmonary capillaries. Positive pressure in expiration serves the function of keeping the bronchi from advanced constriction during expiration and also of applying a direct opposing pressure on the external capillary wall, thereby retarding the tendency toward edema production and directly counteracting the internal hydrostatic pressure within the capillary.

The local application of epinephrine and neosynephrin by inhalation of the nebulized spray allows contact of these substances with the smaller bronchi locally and is frequently effective in causing cessation of bronchial spasm and a decreased swelling of the mucous membrane at a relatively low concentration of the drug in the body.

In order that the patient may benefit from inhalational therapy, the physician should be able to prescribe the concentration of oxygen to be breathed by the patient and, in the newer procedures employed, the amount of positive pressure desired or the proportion of helium in a helium-oxygen mixture.

OXYGEN REGULATION AND GAGES

Oxygen should be employed in high pressure tanks of 244 cubic feet or 6905 liters capacity. There is no justification for the use of low pressure tanks since there is no special "medical" oxygen and since only small quantities of oxygen can be furnished in this expensive manner. Oxygen used in medical practice is the same as industrial oxygen.

The regulator attached to an oxygen cylinder contains two gages, one which indicates the rate of flow in liters per minute and another which reveals the amount of oxygen in the cylinder. Either a variable orifice float gage or a Bourdon tube spring type regulator gage may be employed, provided the gage chosen is made by one of the reliable standard manufacturers of the equipment. The gage should be tested from time to time by measuring the rate at which the spirometer bell of a metabolism apparatus is filled at standard pressure and temperature. In attaching the regulator to an oxygen tank, the oxygen tank should first be 'cracked,' that is, it should be opened slightly

until the hiss of escaping gas is heard and then quickly closed. This is done to prevent the initial oxygen stream from blowing dust into the regulator.

OXYGEN TENT THERAPY FOR ADULTS

The most comfortable method of providing oxygen therapy, next to the use of the oxygen room, is in a tent with a phiofilm or other transparent canopy. However, if the tent is to fulfil its purpose, it must be able to maintain continuously the desired oxygen concentration, generally 50 per cent. The possibility of leaks developing in a unit is such that no tent should ever be used unless the oxygen concentration of the atmosphere is tested at least two or three times a day. The test is so simple and yet so essential that no physician should consent to the employment of a tent either in private practice or in the hospital unless provision is made for periodic testing and recording of the oxygen percentage of the contained atmosphere. Although a concentration of oxygen as low as 35 per cent at times will be adequate to correct anoxia, in other instances concentrations as high as 70 per cent may be desirable. It should be possible to fulfil the recommendation of the physician in respect to these oxygen concentrations in any air-tight tent. In a large oxygen tent the administration of a high flow of oxygen, for example 15 liters a minute, will result in a concentration above 50 per cent oxygen in thirty minutes. If two tanks are employed with a total inlet of 30 liters a minute concentrations in excess of 50 per cent are obtained in fifteen minutes. When the patient is removed for examination or when for other reasons the tent canopy is opened, an increase in the flow of oxygen is indicated. There will be a saving in oxygen if the blower is stopped when ice is added to the unit.

In order to provide maximal comfort the tent should generally have a capacity of more than 8 cubic feet. The temperature inside the tent should be maintainable at the desired level by means of a cooling device. For most patients with fever a temperature between 58 and 68 F is preferred in winter and slightly higher temperatures in summer. For older patients and infants higher temperatures are often desirable. The relative humidity should generally be maintained at between 40 and 60 per cent. When tents are ventilated by motor blown circulation which forces the air over ice, the humidity will usually be within this range. In certain conditions, such as tracheobronchitis, higher humidities and temperatures than are normally employed may be desirable. If this is the case, the circulation of the atmosphere should be lowered and the quantity of ice decreased. A spark-proof vaporizer is being developed at this time in conjunction with tent therapy. The technician should be instructed to observe and record the temperature in the tent. If the temperature goes above 70 F, the indication is that there is inadequate cooling and consequently inadequate removal of moisture also. This may be due to slow circulation of the motor blower, too little ice or ice in such small pieces as to retard circulation. Ice should be inserted in chunks the size of a grapefruit.

Within the last decade it has become apparent that the maintenance of an oxygen flow necessary to keep the oxygen concentration in a general range of 50 per cent requires a minimum flow of 9, and preferably 10, liters of oxygen a minute. This is sufficient to wash out most of the carbon dioxide produced by

the patient, so that the carbon dioxide concentration is rarely above 1.5 per cent. The absence of soda lime constitutes a saving both in cost of the chemical and in the expense of supervision sufficient to compensate for the increased flow of oxygen. As a matter of fact, if lesser rates of oxygen flow are maintained and soda lime is used, there is considerable difficulty in keeping the oxygen concentration at an effectively high level, especially for patients who are seriously ill and require treatment within the tent. Because there is no valid indication for continuous stimulation of the respiratory centers, addition of carbon dioxide to oxygen is not required for most illnesses.

The oxygen concentration of the atmosphere should be tested at frequent intervals and the carbon dioxide percentage in the tent should be tested in each unit under the conditions in which the tent is ordinarily operated. Provision should also be made to test the relative humidity in the tent although when the functional capacity of a motor blower tent has once been appraised this need not be performed daily.

In thermal circulation tents a concentration of 50 per cent may frequently be obtained by an oxygen flow below 9 liters a minute but with the inevitable accumulation of increasing concentrations of carbon dioxide as the flow is lowered below 8 liters a minute. Since a soda lime absorber would have to be added if low oxygen flows (under 8 liters) are employed, it is preferable to administer from 9 to 10 liters of oxygen a minute and give the patient the benefit of the higher oxygen concentration without the physiologic disadvantage of excess carbon dioxide in the inspired air and also without the added need for frequent carbon dioxide testing.

A closed canopy should not be put over a patient's head unless it is equipped with an adequate cooling and dehumidifying apparatus.

Although rubber or canvas canopies are still employed, the psychologic advantages of completely transparent canopies are such as to make the indication for the latter type of tent covering a strong one. Phiofilm or a suitable substitute should be used if obtainable. The modern tent is and should be noiseless and a red light or other mechanism may be provided which remains on as an indication that the motor blower is in action.

OXYGEN TENT THERAPY FOR INFANTS

The same general principles apply to tents for infants, except that higher temperatures and higher humidities should be prescribed for very young infants. Furthermore, smaller tents may well be used. It should be recognized that infants deprived of heat by rapid circulation of cold atmosphere over them may have an abrupt fall in body temperature. A tent with an aperture at the top and with provision to admit oxygen may be used provided it is not placed near an open window or door where air currents may blow out the accumulated oxygen. It is desirable in these tents to test the oxygen concentration at a point at the level of the infant's nose. Because of the fact that infants produce so little heat water and carbon dioxide, open top tents without an air conditioner may be employed. When closed canopies and motor driven air conditioned tents are used, the motor should be run at low speed and either no ice should be placed in the unit or only the small amount desired for the prescribed conditions of temperature and humidity.

STERILIZATION OF THE OXYGEN TENT

After the termination of each case the tent used should be washed with soap and water both inside and outside. It should then either be dipped in a solution of 1:10,000 mercuric bichloride or any other efficient sterilizing solution for five minutes and washed with water or, preferably, rubbed down with 70 per cent alcohol, which is the more common practice. The use of the phiofilm canopy permits frequent replacement of it in private practice.

FIKE HAZARDS

All tents should be conspicuously labeled "Danger No flames No sparks." When a tent is used within a private room, it is desirable to place on the door a sign with a similar label. Oxygen regulators should also be conspicuously stamped "Do not oil." It is suggested that noninflammable phiofilm material be used in the construction of tent canopies.

Smoking should not be permitted in the room in which oxygen therapy is being conducted. No electric heating pads or electric call bells should be permitted in oxygen tents. Visitors should be warned by word of mouth not to light matches and to observe the regulations, since some do not speak English or do not read the instructions.

NASAL CATHETERS

There are several effective methods of administering oxygen through the nose by employing a nasal catheter either in the nasopharynx or in the oral pharynx or, in some instances, by the use of a nasal metal tube which just enters each nostril. A soft rubber nasal catheter is generally preferred to the metal nasal tube. The oxygen is first passed through approximately 3 inches of water to prevent drying of the mucous membranes. A 1/8" boric acid nasal catheter number 10 or 12 French is inserted into the nostril for a distance of approximately 3 inches, that is, up to but not touching the posterior wall of the nasopharynx. Five liters of oxygen a minute generally provides 37 per cent oxygen in the inspired air. A single catheter may be changed from one nostril to the other if irritation should occur. The terminal inch of the catheter should be perforated with four small holes in order to prevent a single stream of oxygen impinging on one localized area of the mucous membrane.

If the catheter is passed down into the oral pharynx opposite the glottis, a concentration of 42 per cent oxygen may be obtained in the inspired air at a flow of 5 liters a minute. When the catheter is used in the oral pharynx, it is important to remember that oxygen may pass into the stomach and distend the abdomen if the catheter is placed lower than the uvula. If the pharyngeal position of the catheter is adopted, 7 liters of oxygen a minute to supply concentrations of oxygen in excess of 50 per cent may be used with no sensation of discomfort is produced. The nasal catheter should be lubricated with KY jelly or petrolatum each time it is inserted. The catheter should be removed at least twice in twenty-four hours for cleaning and, at the termination of the case, should be cleansed and sterilized. This is important, as otherwise the small holes in the terminal inch of the catheter may be plugged and oxygen may escape through one single orifice, thus producing irritation of the nasal mucous membrane. When a patient after insertion

of the catheter in the oral pharynx, swallows a bolus of air, the inference is that the catheter has been inserted too far, it is then withdrawn until no gas is taken into the stomach during deglutition.

OXYGEN MASKS

Oxygen masks are especially suitable for administration of high concentrations of oxygen from 50 to 100 per cent. For application in either the nasal or the oral pharynx, the nasal catheter is generally more comfortable for long continued use and just as effective as the oxygen mask if concentrations below 50 per cent are prescribed. The oxygen tents with transparent canopies and air conditioning cabinets are generally more comfortable for the administration of moderate oxygen concentrations, such as between 40 and 60 per cent. Within recent years it has become apparent that pure oxygen is not irritating to human pulmonary epithelium when administered by a mask for two days, and in all probability for four days. The fact that the mask is removed from time to time in order to provide food or that the face may be washed or for other reasons may be responsible for this exceptional tolerance of 100 per cent oxygen. At any rate, the previous warnings regarding the danger of pulmonary edema from inhalation of these very high oxygen atmospheres were based on experiments on animals which were kept in air-tight chambers continuously for three or four days. Since clinical evidence has been forthcoming from a number of hospitals indicating that concentrations of oxygen between 70 and 100 per cent have been used without damage to the lung for periods of from two to five days, there has been opened a new field for the mask in which a large increase in physically dissolved oxygen may be of crucial value in such conditions as shock, severe hemorrhage and imminent cardiac failure.

There are two masks available, the B. L. B. (Boothby-Lovelace-Bulbulian) and the Burch-Eckmann injector meter mask. In the B. L. B. mask a well fitting rubber nasal or oral nasal mask is attached to the face and from it is suspended a small bag in which a moderate amount of rebreathing takes place. Two sponge rubber disks placed in the center of the mask serve as a combination inspiratory and expiratory valve. During inspiration there is sufficient resistance in the sponge rubber to prevent a free flow of air into the mask. When the rebreathing bag is emptied, air is drawn through the sponge disk. During expiration, first the rebreathing bag is filled with the exhaled air and the remainder of expired air then passes through the sponge rubber disk into the outer atmosphere.

During increased ventilation, as in severe dyspnea, the resistance imposed by breathing through the sponge rubber is naturally increased. This is especially significant during the inspiratory cycle if flows of oxygen under 6 liters a minute are used. It must also be pointed out that a flow of oxygen at a rate as low as 2 to 4 liters a minute will be accompanied by sufficient rebreathing to produce a carbon dioxide percentage in the inspired air of approximately 2 per cent. With this mask it is generally desirable to use a high flow of oxygen, as at the rate of from 7 to 10 liters a minute, in order to eliminate the inspiratory resistance and the increased carbon dioxide in the inspired air.

In the injector mask a delicate inspiratory valve is placed between the mask and a large light latex bag

which prevents any rebreathing and simply serves as a collecting bag for oxygen. A light rubber flutter expiratory valve is placed in front of the mask for exit of the exhaled atmosphere. This mask operates at minimal resistance during both high and low oxygen flows. An injector is attached to the regulator, which makes possible the administration of any oxygen concentration desired from 40 to 100 per cent. By use of different sized apertures in the injector, a variable amount of atmospheric air is pulled into it because of the negative pressure created by the stream of oxygen passing through it into the rubber tubing. Calibration of these orifices makes possible the instantaneous provision of the desired oxygen concentration with an error of not more than ± 3 per cent. If the administration of low flows of oxygen and the exclusion of carbon dioxide in the inspired air are called for, the injector mask is most suitable for this purpose. If carbon dioxide of varying percentages is prescribed, the inspiratory valve in this mask may be removed to allow rebreathing, or the B. L. B. mask may be employed. The latter mask may be obtained in two sizes. It is essential that in cases presenting obstructive dyspnea a minimal inspiratory resistance is present. The rate of flow of oxygen from the regulator may be varied from 4 to 15 liters a minute, depending on the concentration of oxygen desired and the desirability of avoiding resistance from the apparatus itself. The employment of less than 4 liters a minute is rarely indicated except for young children, for whom lower flows may be adequate.

Although these newer types of masks are comfortable for a large number of patients, it must be recognized that their continuous use becomes objectionable to a good many others. When discomfort prevents the continuous administration of oxygen by mask, a shift should be made to the oxygen tent, if it is feasible, or, if not, to the nasal catheter.

After use, the mask should be scrubbed thoroughly with soap and water and boiled, or immersed or washed in a 70 per cent alcohol solution.

THE OXYGEN MASK METERED FOR POSITIVE PRESSURE

The injector mask may be obtained equipped with a metal disk which surrounds the expiratory flutter valve and contains on its external surface five orifices of different diameters. When the largest sized orifice is employed, expiration proceeds naturally without pressure. When the disk is turned to the orifices of smaller size, the patient exhales under a positive pressure of 1, 2, 3 or 4 cm. of water, depending on the size of the orifice.

Provision of positive pressure during expiration is specifically indicated for the treatment of pulmonary edema, either during the course of cardiorespiratory illness or as a specific remedy for pulmonary irritants, such as chlorine gas or the fumes of nitric acid. In treating pulmonary edema it is customary to begin with high pressures, such as 4 cm., and gradually lower the pressure to 2 and 1 cm. of water. From 40 to 100 per cent oxygen is employed. The injector attached to the regulator is turned to the oxygen percentage desired, and the flow from the regulator is adjusted at that rate which prevents the collecting bag from collapsing at the end of inspiration. It is desirable to have the injector one third full of water so that the

stream of oxygen may pick up some moisture as it passes into the mask.

The relative humidity of pure oxygen passing at a flow of from 8 to 10 liters a minute through the injector partially filled with water is approximately 20 per cent at 70 F. The inspired oxygen is additionally moistened by the inner surfaces of the mask, which are wet with the saturated water vapor resulting from expiration, so that the ultimate relative humidity of the inspired oxygen is approximately 45 per cent. If a still higher relative humidity is desired during inhalation of 100 per cent oxygen, the injector is removed and a water bottle attached to the regulator, so that the stream of oxygen will pass upward through at least 3 inches of water before entering the mask.

Positive pressure is employed also to prevent or control the oozing that takes place from the tracheo-bronchial tree following tracheotomy in cases of previously existing laryngeal obstruction. In this instance the tracheotomy tube is prolonged so that inspiration may take place through a flutter valve and expiration proceed through an expiratory valve into a water bottle at pressures which generally begin at from 4 to 5 cm. of water and are gradually lowered during a period of twelve hours to from 1 to 2 cm. of water.

Positive pressure respiration appears to be contraindicated in shock in which the venous return to the heart is retarded. The increased intrapulmonary pressure of from 2 to 4 cm. of water may further diminish the flow of blood into the right auricle. When peripheral circulatory failure is suspected the blood pressure should be followed at fifteen minute intervals and the pressure reduced or discontinued if a fall greater than 10 mm. of mercury takes place in the systolic pressure following application of breathing under positive pressure.

THE HELIUM-OXYGEN HOOD

Although helium-oxygen therapy may be carried out by means of mask oxygen apparatus, the helium-oxygen hood is the only effective apparatus for administering from 20 to 30 per cent oxygen and from 80 to 70 per cent helium under a positive pressure during inspiration as well as expiration. The apparatus consists of a hood with a removable rubber collar, which fits around the neck, and an air conditioning cabinet. The conditioning cabinet contains two Barolyme carbon dioxide absorbers which are placed in ice water, a motor blower unit and a rheostat for controlling the velocity of air circulating through the hood. To the hood is attached a pressure control water valve that consists simply of a rubber tube with a glass connection leading into a water bottle. The length of the glass tube immersed in the water determines the pressure to which the head of the patient, and therefore the intrapulmonary respiratory passageway, is exposed. This apparatus is employed for the treatment of severe bronchial asthma and for obstructive dyspnea produced by lesions in the tracheobronchial passageway.

Since this is a closed circuit apparatus in which special precautions are taken to avoid all leaks, in order that no nitrogen may be admitted into the helium-oxygen atmosphere, it is especially important to provide efficient cooling and dehumidification and to use a soda lime absorbent to prevent the accumulation of carbon dioxide.

If helium is not available, the helmet may be employed with the administration of 100 per cent

oxygen for the treatment of both asthma and obstructive dyspnea generally. Inhalation of oxygen under pressure during the inspiratory cycle is especially apt to relieve severe dyspnea due to laryngeal or tracheal constriction. The helium-oxygen hood is used also for the treatment of pulmonary edema, at first with a relatively high pressure of from 5 to 6 cm of water, then with pressures gradually reduced to 2 and 1 cm, and finally to atmospheric pressure.

Since helium is an inert gas it should not be employed without previous admixture with oxygen in tanks containing 20 to 25 per cent oxygen and 80 to 75 per cent helium respectively. If separate tanks of oxygen and helium were employed to supply a hood or mask apparatus, inadvertent stoppage of the oxygen supply would result in progressive elevation of the helium concentration of the contained atmosphere, with danger of asphyxia to the patient.

THE ADMINISTRATION OF 5 TO 10 PER CENT CARBON DIOXIDE IN OXYGEN

The administration of 5 to 10 per cent carbon dioxide in oxygen is useful in carbon monoxide poisoning and other clinical conditions such as electric shock, morphine poisoning and drowning in which the respiratory center may be depressed. Carbon dioxide-oxygen inhalation has also been employed in massive collapse of the lungs, in order to stretch the bronchi and perhaps loosen a tenacious plug of mucus, and for short periods after operations to expand the lungs and bronchi in the belief that atelectasis may be less likely to take place. It is particularly useful in intractable hiccup. For this purpose a tank of either 90 per cent oxygen and 10 per cent carbon dioxide or 93 per cent oxygen and 7 per cent carbon dioxide may be employed either with a B. L. B. or an injector mask for short periods of two or three minutes or until an increase in pulmonary ventilation has taken place sufficient to relieve the condition for which it was intended. It must be borne in mind that prolonged administration of carbon dioxide will bring about toxic symptoms, such as headache, nausea and, if concentrations above 10 per cent are employed too long, convulsions.

ADMINISTRATION OF VAPORIZED SOLUTIONS OF EPINEPHRINE AND NEOSYNEPHRIN HYDROCHLORIDE

It has been found convenient to use a nebulizer with a hand bulb to vaporize 1:100 epinephrine and 1 per cent neosynephrin hydrochloride. Since the vaporization of relatively large amounts of these drugs has been shown to be valuable in the treatment of severe bronchial asthma, the high pressure tank rather than the hand bulb should be used. One cc of 1:100 epinephrine or 1 cc of 1 per cent neosynephrin hydrochloride may be inserted into one of the openings in a glass nebulizer and a tube from an oxygen tank connected to the glass outlet. The oxygen from the tank is then turned to 5 liters a minute and the wide end of the nebulizer held between the teeth with the mouth wide open. The nebulizer is rinsed with warm water after use to prevent clogging. It is generally desirable to use a warm mouth wash and gargle after spraying with epinephrine solutions to prevent drying of the throat. This method of supplying the bronchi and alveoli with nebulized solutions may be used for the administration of other drugs, such as diamino-sulfone glucoside.

TECHNICIANS

The technics of inhalational therapy must be skilfully administered if use of the therapy is to be of benefit to the patient. Because of the complexity and diversity of the more modern apparatus, many physicians prefer to have technicians attend to the mechanical details involved. Such technicians should be properly trained and supervised. It is therefore suggested that appropriate courses be given for the training of inhalational therapy technicians and nurses who assist in these procedures.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS PREVIOUSLY PUBLISHED ITS CONSIDERATION OF A COD LIVER OIL PREPARATION (THE JOURNAL OCT 24 1936 P 1384) BUT BECAUSE OF RENEWED INTEREST IN THIS CLASS OF AGENTS FOR THE TREATMENT OF BURNS AND THE ACCELERATION OF WOUND HEALING AND IN THE VALIDITY OF CERTAIN ADVERTISING CLAIMS PUBLICATION OF THE FOLLOWING STATUS REPORT WAS DEEMED ADVISABLE. THIS REPORT REVEALS THAT MUCH WORK HAS BEEN PUBLISHED ON THE SUBJECT BUT UNFORTUNATELY, THE LACK OF ADEQUATE CONTROLS OR REPORTS ON SUCH CONTROLS, HAS HINDERED GREATLY A TRUE EVALUATION OF THE STATUS OF COD LIVER OIL IN THE MEDICAL ARMAMENTARIUM AS FAR AS TOPICAL APPLICATION IS CONCERNED. WHILE SOME INTERESTING OBSERVATIONS HAVE BEEN RECORDED CONSIDERABLE EXPERIMENTATION REMAINS TO BE DONE. IN VIEW OF THE CURRENT CONFLICTING OPINIONS AND LACK OF SUBSTANTIATING EVIDENCE THE COUNCIL IS OF THE OPINION THAT THERE REMAIN TOO MANY UNANSWERED QUESTIONS TO WARRANT ACCEPTANCE OF COD LIVER OIL PREPARATIONS FOR EXTERNAL USE AT THIS TIME BUT IT PRESENTS THE FOLLOWING STATEMENT TO OFFER TO THE MEDICAL PROFESSION A CONCISE REVIEW OF THE PRESENT STATUS OF SUCH MEDICAMENTS AND TO SUGGEST THE NEED FOR FURTHER CAREFULLY CONTROLLED OBSERVATIONS.

AUSTIN E. SMITH, M.D., Secretary

A STATUS REPORT ON THE EXTERNAL USE OF COD LIVER OIL

Lohr¹ was the first to publicize widely the use of cod liver oil externally. He employed an ointment containing one part of cod liver oil mixed with two parts of petrolatum in treating burns, abscesses, wounds, ulcers and osteomyelitis. He reported unusual success, especially in the rapid epithelization of large areas and the conversion of unhealthy necrotic areas to clean, bacteria free wounds. Lohr stated that he found skin grafting unnecessary even when large areas were denuded. Since the publication of Lohr's original articles, many reports have appeared in the literature. Thus, Lucke² used Lohr's treatment successfully in furunculosis, abscesses, infected wounds and ulcers. Later he added bee honey to the ointment and felt that the results were even better. Buchheister³ also had good results from the latter unguent in infected surgical wounds, furunculosis, carbuncles, osteomyelitis and mastoiditis. Kirschner⁴ disagreed with Lohr's claims. He found zinc ointment to be more effective than cod liver oil, which he reported as actually harmful in some instances. He marked as false the conclusion that under local cod liver oil treatment all wounds epithelize and no skin grafting is necessary. Steel⁵ employed

gauze saturated with crude cod liver oil in the treatment of minor and severe burns and found it suitable for indolent ulcers, deep abrasions and infection. He believed the higher the vitamin content the better the results and used his crude cod liver oil treatment routinely for burns. Schaer⁶ found cod liver oil satisfactory in the secondary healing of wounds but felt that its use in osteomyelitis required further investigation. Balachowski and Ratchevski⁷ and Balachowski⁸ used carotene in a paraffin base for burns. Iost and Kochergin⁹ employed a cod liver oil ointment in 263 cases of superficial and suppurating wounds, open amputation stumps, ulcers, frost bites and traumas. Mason¹⁰ advocated cod liver oil to stimulate indolent burns. On the other hand MacCollum¹¹ used cod liver oil and other unguents in unhealed burns and found that all had about the same effect. Wakeley,¹² in discussing war burns, spoke among other forms of treatment of cod liver oil for burns of the face. Meherin and Schoemaker,¹³ reporting on the treatment of cement burns stated that once clean granulations have started, cod liver oil ointment should be used. Driver, Binkley and Sullivan¹⁴ used an ointment containing cod liver oil 88 per cent and white wax 12 per cent and an ointment of white petrolatum to which was added 2000 U. S. P. units of oil soluble carotene per gram. They treated 25 cases of varicose ulcers, 4 of erythema induratum and 3 indolent ulcers. The results were generally more satisfactory than those obtained by other methods. Stevenson¹⁵ has reported good results with cod liver oil ointment in the treatment of burns of the cornea, eyes and lids. Hardin,¹⁶ after reviewing the entire subject and reporting his own experience in 396 cases of various types of wounds felt that cod liver oil ointment was an effective method of local wound therapy. Such treatment according to this author, is applicable to both clean and infected wounds and to new and old burns of major severity. Aldrich¹⁷ found cod liver oil ointment to give excellent results in the treatment of burns, wounds, indolent ulcers and pruritus ani and vulvae while Brandaleone¹⁸ reported that such ointments promote the healing of ulcers of the feet in patients with diabetes.

Many similar clinical reports could be cited. In general such reports stress the impression that cod liver oil applied locally produces a definite leukocytic response with rapid liquefaction of necrotic material, suppression of local infection and stimulation of granulation tissue and of epithelization with rapid healing and minimal scarring. Unfortunately well controlled clinical investigations are remarkable by their scarcity, while only a few studies of the comparative effect of cod liver oil in promoting the healing of experimental wounds in animals have appeared. Puestow, Poncher and Hammatt¹⁹ showed that burns in guinea pigs and rabbits healed 25 per cent faster under cod liver oil therapy than with tannic acid. There was no indication in this report that the results obtained were statis-

tically significant. Getz²⁰ found that experimentally produced tuberculous skin lesions in guinea pigs healed more rapidly when treated with cod liver oil than when treated with paraffin, lanum or cottonseed oil. Brandaleone and Popper²¹ found the rate of healing of elliptical wounds in vitamin A deficient rats (produced by clipping away a portion of the skin with scissors) significantly higher if cod liver oil was locally applied or given orally than if the wounds were untreated or treated with linseed oil. No significant differences in the rate of healing of such treated and untreated wounds in normal rats was found. Puestow and his collaborators¹⁹ could find no histologic evidence that the scars of healed burns following treatment with cod liver oil were different from those following other treatment. Brandaleone and Popper²¹ studied microscopically the scars occurring in their animals but report no differences which may have occurred as a result of varying treatments.

The mechanism of any local action which cod liver oil may produce remains unknown. Most clinical reports, beginning with those of Lohr, have assumed on an empiric basis that the activity noted was due to the vitamin content of the oil. Lohr and Unger²² tested the efficiency of various cod liver oil fractions in promoting the healing of experimental wounds in guinea pigs. No data were given, but they concluded that cholesterol, squalene and saturated fatty acids were ineffective while vitamins A and D and the unsaturated fatty acids promoted healing. Concentrations of the vitamins higher than those found in cod liver oil were said to be detrimental. Lauber²³ found that vitamin A applied locally produced no acceleration of wound healing and in concentrated amounts retarded it. He also reported that, while small quantities of vitamin D produced a slight acceleration, large doses inhibited it. Roth²⁴ found that the local application of oils containing vitamin A prevented or cured the keratomalacia of vitamin A deficient rats. However, cod liver oil treatment caused no more rapid healing of artificially produced abrasions of rabbits' corners than did liquid petrolatum. Getz²⁰ fractionated cod liver oil in an effort to determine the principle responsible for the more rapid healing of tuberculous ulcers in guinea pigs. The fatty acid fraction of the cod liver oil was found to be nonhealing. The active agent was concentrated in the "non-saponifiable residue," since experimentally it caused faster healing than the whole oil. This non-saponifiable residue was further fractionated. The precipitate of heavy sterol was found to be inert, and the filtrate designated the "vitamin fraction" proved to be active. This so-called vitamin fraction had two known constituents—vitamins A and D—and numerous unknown substances. The author compared as to healing properties three different oils, varying greatly in their content of vitamins A and D: halibut liver oil with 50,000 A and 200 D units; turn liver oil with 70,000 A and 88,000 D units; and cod liver oil with 1,800 A and 175 D units per gram. Assuming the oils to be comparable in other respects, if vitamin A was the factor, halibut and turn liver oils should have been more effective. While, if vitamin D was the desired agent, turn liver oil should have been best. Cod liver oil proved to be superior to either of the other agents. In the report of Puestow and his collaborators¹⁹ the healing of electrocautery burns (in pigs and rabbits) was studied following treatment with various vitamin containing oils. While the cod liver oil treated lesions healed 25 per cent faster than those untreated or treated with 5 per cent tannic acid or olive oil, those treated with ointments of varying vitamin content showed approximately the same healing as with cod liver oil. These high vitamin ointments were one containing no vitamin A but containing irradiated ergosterol in oil to give 625,000 units of vitamin D per gram of ointment, one containing fish liver oil to give 28,250 units of vita-

mm A and 46,875 units of vitamin D per gram of ointment, and one containing fish liver oil to give 237,500 units of vitamin A and 1,250 units of vitamin D per gram of ointment. The ointment containing irradiated ergosterol gave startling evidence of toxicity when used on rabbits. 13 of 15 such animals died in less than a week. Dann, Glücksmann and Tansley,²⁵ using techniques and standards considerably more rigid than in most such reports, studied the rate of collagen and epithelial regeneration of "standard" wounds in rats when treated with various agents. The rapidity of healing of such wounds when untreated was compared with that seen when the following oils were used as a local treatment: cod liver oil (two samples), the distillate and the residue of a molecular distillation of cod liver oil, vitamin A naphthoate, vitamin A in coconut oil, coconut oil, peroxidized Arachis oil, Arachis oil, linoleic acid, methyl linoleate, and liquid paraffin. In most cases 12 or more animals were used in each group. It was found that collagen regeneration was stimulated to a varying degree by all the substances. Hypertrophic collagen regeneration after Arachis oil interfered with epithelial regeneration. Epithelial regeneration was promoted by linoleic acid only; it was delayed by all other substances except liquid paraffin and one sample of cod liver oil. Such results cast grave doubts as to whether the local application of vitamins A and D has any effect at all on wound healing, provided always that no general avitaminosis A or D exists. The experiments of Brandtcone and Popper²¹ do not answer this question, as local cod liver oil treatment produced no increase in the rate of healing of the normal rats of their series.

Löhr and Treusch²⁶ believed cod liver oil to possess bacteriostatic and bactericidal qualities. They found oil inoculated with staphylococci, streptococci and colon bacilli to be sterile after twenty-four hours. Löhr stated that cod liver oil is always sterile. Tumansky and Yatskevich²⁷ found that growth of streptococci and staphylococci in sterilized and nonsterilized cod liver oil ceased after one hour and six hours respectively. If sterile petrolatum was added to cod liver oil, bacteria grew for seventy-two hours. In sterile petrolatum alone, growth was prolonged for fifteen days. Kummell and Jensen²⁸ examined different specimens of Löhr's preparation (one part of cod liver oil to two parts of petrolatum) and gypsum dressings after their removal, took cultures of them and found no interference with cultural growth. Regularly, cultures from the bottom of the oil deposits were sterile. Fresh superficial wounds treated with cod liver oil showed a bacterial growth. The paper of Driver, Binkley and Sullivan,¹⁴ which showed that cod liver oil required the addition of phenylmercuric benzoate 1:1,000 or phenylmercuric borate 1:2,500 before inhibition of bacteria was produced, suggests that its disinfectant properties are definitely limited. Yet von Drigalski²⁹ claimed that cod liver oil interferes with the growth of organisms cultivated from the ground and from the feces and sputum. Lichtenstein³⁰ found that in a nutrient medium staphylococci succumbed under cod liver oil in two weeks, *Escherichia coli* was resistant to cod liver oil, the addition of vitamins A and D to cod liver oil did not influence its action, and both staphylococci and *Escherichia coli* survived indefinitely under liquid paraffin. In the absence of a nutrient medium, liquid paraffin had no influence on the vitality of the organisms for the time observed (thirty-five days), olive oil killed bacteria suspended in it in seven to ten days, while cod liver oil had the same effect in seventeen to twenty-two hours and boiled linseed oil in one to one and one-fourth hours.

Irradiated cod liver oil had a greater bactericidal effect under such conditions than before irradiation. The author found an inverse relationship between the length of time required to kill the bacteria and the amount of peroxide present in these oil preparations. He was unable to rule out the possibility that other substances might play a part.

There are differences of opinion in the literature concerning the strength of cod liver oil which should be employed in ointments applied locally. With no conclusive evidence on which to base their opinions, most workers apparently feel that the higher the percentage of cod liver oil, up to 80 per cent, the better the ointment.

The complete immobilization of the affected part was an integral part of the treatment described by Löhr. Hardin¹⁶ stated that his conception of the cod liver oil treatment of wounds closely resembles Orr's closed petrolatum treatment of compound fractures³¹ and the closed plaster treatment of war wounds described by Trueta.³² Many other reports indicate that the success of cod liver oil dressings is dependent in part on such immobilization and the fewer dressings required. The relative freedom from pain during the changing of dressings is thought by some to be a factor to be considered. MacCollum¹¹ thought the pressure dressings more important in the treatment of burns of children than the type of ointment used.

Most writers emphasize that the use of cod liver oil does not invalidate the accepted methods of routine wound care such as careful debridement, maintenance of blood volume, combating anemia and treatment of general disease. Hardin¹⁶ warns that cod liver oil must be used with judgment in badly contaminated wounds and is not immediately applicable to acute inflammatory lesions, where the usual surgical measures are indicated. Finally, it is agreed that early skin grafting is, above all, a necessity.

In summary, it may be said that there is a significant number of clinical reports favorable to the use of cod liver oil ointments in the local treatment of burns of all types, of wounds and of ulcers. Burns in the "indolent stage" and indolent ulcers are said to be especially benefited by local cod liver oil treatment, when dressings are left in place forty-eight hours. Most workers are agreed that local infection diminishes, necrotic material is liquefied and growth of granulation tissue and epithelization are stimulated. Unfortunately there is a surprising and regrettable lack of control in such studies. The difficulty of evaluating such reports is emphasized by the Youngs and Fisher,³³ who criticized the common practice of basing claims on insignificant data without respect to the biologic variations which count so much in the healing of a wound. The few experimental studies reported are not conclusive, indeed, the more recent and better controlled work on animals has failed to show any advantage of cod liver oil ointment over other ointments. The therapeutic constituents of cod liver oil aside from vitamins are still unknown. The concept that the possible stimulating properties of cod liver oil rest in its vitamin content is purely empiric, studies predicating the bacteriostatic and bactericidal activity of cod liver oil are controversial. Few reports of toxicity from the use of cod liver oil ointments have appeared. It is apparent that such ointments can serve the function of a stimulating ointment and several reports attest their beneficial effect on indolent ulcers. However their use should not violate recognized surgical principles, such preparations do not obviate the necessity for early and careful skin grafting or of other recognized medical agents for the treatment of burns and wounds.

At the time of considering this report the Council had before it the presentation of two commercially available cod liver oil preparations for topical application. After due consideration the Council voted that any favorable action on such agents must await further evidence. Accordingly, the firms were notified of the Council's decision.

SATURDAY, MARCH 6, 1943

THE MEDICAL DEPARTMENT OF THE ARMY

When the medical history of World War II is written the year that elapsed following the treacherous attack by Japan at Pearl Harbor will be recognized as one in which the Medical Department of the United States Army was expanded tremendously in personnel, organized units, supplies and responsibilities and in which it met all these demands quietly and efficiently. Now with more than thirty-five thousand medical officers with hundreds of thousands of medical corps men, with double the number of general and station hospitals and well-nigh triple the bed capacity, it stands ready to meet any new obligations that may be placed upon it. During the year the only serious incident from a medical point of view was the jaundice associated with inoculation against yellow fever. The first week of February 1943 found atypical pneumonia and meningitis most prominent of the infectious diseases but even these were scattering with a few cases here and there and only a score or slightly more of cases of either in the few camps most seriously affected. From July 1942 the maximum admissions for venereal disease had reached less than 1 per thousand, and admissions for both gonorrhea and syphilis had fallen in February 1943 below levels of November 1942.

The remarkable records here cited are the actual evidence of the effectiveness of the organization of the Office of the Surgeon General to meet every contingency. In January 1941 a Central Epidemic Control Board was established including such specialists from civilian life as Drs. Francis G. Blake of Yale, O. H. Perin Pepper, Pennsylvania, Alphonse R. Dochez, Columbia, E. W. Goodpasture, Vanderbilt, Kenneth F. Mancy, Johns Hopkins, A. J. Warren and Wilbur F. Sawyer of the International Health Division of the Rockefeller Foundation, Oswald T. Avery of the Rockefeller Institute and E. S. Robinson of the Massachusetts Department of Health. A special commission on influenza is headed by Dr. Thomas Francis Jr. of Michigan, one on pneumonia by Colin M. McLeod of New York

University, one on hemolytic streptococcus disease by M. H. Dawson of Columbia, one on measles by Joseph Stokes Jr., Pennsylvania, one on meningitis by Perrin Long, Johns Hopkins, and one on neurotropic virus diseases by John R. Paul, Yale. Dr. Stanhope Bayne-Jones of Yale heads the commission on epidemiologic survey.

To head services in the Office of the Surgeon General have come Brig. Gen. Hugh Morgan of Vanderbilt for medicine, Brig. Gen. Fred Rankin for surgery, Col. Esmond R. Long for tuberculosis. The manner in which these distinguished physicians from civilian life have been drawn into military service in positions of leadership, along with Brig. Gen. Elliott Cutler, now abroad, and many others who serve in organized units has been an inspiration to the many thousands of young men who know that they will find standards of medical service in our armed forces well up to those of civilian practice.

Notwithstanding the speed with which this great medical army has been assembled, the difficulties of adjustment of personnel have been slight. Col. George Lull, whose report was published in *THE JOURNAL* last week, has merited the friendship now held for him by many thousands of civilian physicians who would have found transition to a military status far more difficult without his unfailing tact and courtesy.

Under Brig. Gen. C. C. Hillman, professional services have been standardized utilizing the wealth of talent assembled by the Division of Medical Sciences of the National Research Council. Facilities have been organized by which every person entering the military service is given an x-ray examination of the chest and the roentgenogram is filed permanently with his record. Hundreds of thousands of young men of doubtful physical status have had their records reviewed by this division.

Under Col. James S. Simmons epidemiologic studies have been made which will lead to adequate protection of our young men regardless of the theater of war into which they may be called. Far too often the public thinks of the army doctor only as one who treats wounds on the battlefield. However, insect control, delousing, sanitary dishwashing, development of safe water supplies, selection of clothing for various climates, occupational hygiene and venereal disease control come also under the medical department. Then too the dental division, meat and dairy inspection, care of animals, nursing and physical therapy are parts of the complex organization which has functioned so efficiently under Surg. Gen. James C. Magee in the year of war that has passed.

Today wintertime ailments such as colds, influenza, pneumonia and measles are well below the five year average rate of cases in the Army, even though rates for the civil population in some parts of the country are above the five year average for the country. Venereal disease is substantially less than during World

War I, and the syphilis rate is the lowest in the history of our army. Since January 1941 and up to now, excluding battle casualties, the death rate has been the lowest in the history of our army. During World War I, 1 patient of each 3 with meningitis died, now only 1 in 20 dies. Prompt diagnosis, efficient care and sulfonamides have made the difference. Overseas such conditions as malaria and dysentery are being fought with all that modern medicine has provided for the army medical armamentarium.

The information here made available should be comforting to the American fathers and mothers who have given their sons to the defense of our nation. It is information which should be spread widely so that it may reach the millions of homes in which it will answer questions that have been raised again and again in the family councils. Indeed, if there has been any one obvious deficiency it has been the failure of the Public Relations Division of the United States Army to provide the information that the people want regarding the health of our army, week by week, month by month. Let the people know about the hospitals that have been provided, let them hear about the quality of the physicians enrolled and the medical service that they render, tell about our magnificent record in the treatment of burns and wounds and in the control of malaria, tell of the training programs for thousands of surgical, laboratory, x-ray and other technicians. What about some of the research projects in which the Army has cooperated with the Navy and the Committee on Medical Research? The record of the U S Army Medical Corps is one in which we may all take pride, the public that we serve needs to hear of its accomplishments.

CHEMOTHERAPEUTIC AGENTS AND EXPERIMENTAL TUBERCULOSIS

The usefulness of chemotherapy in the treatment of some infectious diseases has strengthened the belief that chemical compounds may yet be found which will effectively combat the tubercle bacillus. The development of the sulfonamides has increased the fervor of those who seek such chemical weapons.

In 1938 sulfanilamide itself was found to exert an inhibitory effect on the development of tuberculosis in the highly susceptible guinea pig.¹ The drug did not prevent completely the growth of the bacilli, but fewer organisms and less extensive lesions were observed in the treated animals. Toxic doses of the chemical were required to achieve this result. The sulfone promin² has also been reported to have a notable inhibitory effect on the course of the disease in guinea pigs.⁴ In the

meantime a number of sulfonamides and related compounds have been studied with regard to their effect in experimental tuberculosis.

A recent report of Smith and his collaborators⁴ of the National Institute of Health merits especial attention because it deals with a large number of compounds, including sulfonamides, sulfones and comparable phosphorus containing compounds, and because it serves as a progress report on the problem of chemotherapy in experimental tuberculosis. Therapeutic tests carried out by these investigators on experimental animals infected with a virulent human strain of tubercle bacilli showed a favorable effect with the three drugs diaminodiphenylsulfone, promin and sulfadiazine as regards both the survival time and the retardation of progress of the disease. The mortality of an untreated group of infected animals was 81 per cent after one hundred and seven days, while the comparable percentage mortality of animals treated with promin was 44 and of those treated with either of the other drugs was 56. Notably the extent of tuberculous involvement, as indicated by examination of several organs, was found to be much less in the animals treated with diaminodiphenylsulfone than in animals of the other groups. Indeed, many of the animals in the former group presented an uninterrupted growth curve after cessation of treatment, indicating attenuation of the tubercle bacillus or arrest of the infection. As pointed out by Smith and his co-workers, the toxicity of diaminodiphenylsulfone, which exerts its effect at 50 to 75 per cent of the lethal dose, makes it desirable to develop derivatives capable of producing the same or better effects with dosages further removed from the toxic level. According to these investigators promin does not fulfil this requirement but appears to be a step in the right direction. It is perhaps pertinent to mention that a phosphorylated derivative of diaminodiphenylsulfone has recently been prepared which, on the one hand, possesses only one-half to one-fifth the toxicity of the parent sulfone and, on the other hand, has a chemotherapeutic action against experimental pneumococcal infection which is superior to that of the original sulfone.⁵ Whether or not this phosphorylated derivative will prove effective against experimental tuberculosis remains to be seen.

Work on the problem of chemotherapy in experimental tuberculosis is still in the early stage. The more recent attacks on the problem have however, yielded encouraging results and further developments are awaited. It is hardly necessary to point out here that tuberculosis induced experimentally in guinea pigs is dissimilar to tuberculosis in human beings. The prog-

ress of studies on the chemotherapy of tuberculosis in experimental animals is, nevertheless, of obvious importance. While the results of these investigations and the conclusions based on them cannot be directly applied to chemotherapy of tuberculosis in man, they do lead the way in the study of the latter problem.

THE NATIONAL CONFERENCE ON PLANNING FOR WAR AND POSTWAR MEDICAL SERVICES

Elsewhere in this issue (p 769) appears an announcement of a proposed conference on the planning of war and postwar medical services, representing a unique assemblage in American medicine. For the first time a variety of organizations associated with many different aspects of medical services, including scientific advancement, personnel and supplies are meeting to discuss jointly urgent problems which affect all. The organizations which participate in this conference, which has been called under the auspices of the Carlos Finlay Institute of the Americas, include the

American Medical Association
American College of Physicians
American College of Surgeons
American Drug Manufacturers Association
American Hospital Association
American Pharmaceutical Manufacturers Association
American Pharmaceutical Association
American Surgical Trade Association
Wholesale Surgical Trade Association
National Physicians Committee for Extension of Medical Service

The program has been planned in three parts: a morning session concerned largely with epidemic disease and nutrition; an afternoon session concerned with personnel, supplies and research; and an evening program devoted to the ideals that should prevail in working out programs of interest to all the peoples of the world. The evening session has been limited to those specially invited to participate, but the morning and afternoon sessions are open to any physician who may be in New York on March 15 and who might wish to attend. Participation in discussions, however, will again be limited to those especially invited to participate in the conference. Mr. Basil O'Connor, president of the National Foundation for Infantile Paralysis, Inc., and also of the Carlos Finlay Institute of the Americas, an organization which was described in an editorial comment in *THE JOURNAL* on Jan 17, 1942 (p 230), will preside at the evening session.

Significant also in this national conference is the extent to which laymen and statesmen whose interests in medicine have been profound will give of their time and services in developing the contribution of America to the rehabilitation of a starved, disease-ridden and war-torn world.

Current Comment

THE RED CROSS CAMPAIGN

The Red Cross has just begun a national appeal for a special fund of \$125,000,000 to take care of the unprecedented war demands on the organization. The Red Cross supplies the armed forces throughout the world with many comforts and needs not covered by regular military issue. In areas retaken from the enemy, the Red Cross must be and is prepared to supply food, clothing, medicines and other necessities to large numbers of persons, many of whom may be in a starving or otherwise desperate condition. This organization has taken over the procurement of blood for the preparation of plasma for the armed forces as well as for possible civilian disaster. All the material and personnel for these services and others as well must be ready in advance and available when needed. Physicians, more than any others perhaps, are fully aware of the vast humanitarian service of the Red Cross and can be counted on to support this campaign with all the influence as well as financial assets at their command.

EVAPORATED MILK

In recent weeks it has been difficult in some areas to purchase certain brands of evaporated milk. Both mothers and physicians have become concerned as to its availability for infant feeding. The amount of evaporated milk produced in 1942 was in excess of that produced in any previous year. The War Production Board has established a packing quota for 1943 for evaporated milk in 6 ounce and 14½ ounce cans of 90 per cent of the 1942 pack. An additional quantity will be packed in larger containers for institutional and military use. The Food Distribution Administration anticipates that sufficient supplies of evaporated milk will be assured to provide an adequate amount for the needs of children under 2 years of age. However, not all brands will be available in all localities. This situation is obviously not serious, since the composition of evaporated milk has less variation than almost any other canned food. Regulations of the Food and Drug Administration fix and establish definitions and standards of identity for evaporated milk, these became effective July 17, 1940. These regulations require a minimum of 7.9 per cent of milk fat and 25.9 per cent of total milk solids. Since most physicians are concerned as to the possibility that a high percentage of fat in a formula may produce digestive disturbances in infants, the fat content of evaporated milk is of major interest. The regulations establish a minimum, and there is little danger of a fat content much above this minimum. Since fat is the most expensive part of milk, manufacturers are not apt to leave more than the required amount in the product. Consideration should be given of course as to whether or not the milk is irradiated or fortified with vitamin D and to the extent of such fortification so that the milk may be supplemented with this vitamin if necessary. Physi-

cians can do a real service to their patients and then country by explaining to mothers the nature of various brands of evaporated milk, the possible use of other brands for feeding infants, if the one to which they have been accustomed is unavailable, and the special character of irradiated as contrasted with nonirradiated evaporated milk.

MENTAL SYMPTOMS FOLLOWING THE USE OF ATABRINE

The appearance of mental symptoms during or following the administration of atabrine in curative dosage has been reported by many observers. Conoley working in Perak, one of the Federated Malay States, first drew attention to the restlessness and excitement sometimes associated with the taking of atabrine. Other observers in Ceylon, India and Malaya have reported that mental symptoms are noted more commonly in patients treated with atabrine than with those on treatment with quinine. Many of these reports are summarized by J. W. Field in Bulletin 2 of 1938 from the Institute for Medical Research, Federated Malay States. He says that there is a fairly characteristic clinical course of events. Toward the end of the usual five to eight day course of oral atabrine, or perhaps a few days after treatment has been finished, the patient begins to behave strangely, becoming more or less excited, voluble and confused, or occasionally maniacal. He is mentally disturbed for about a week and gradually returns to normal without special treatment. This clinical picture, or atabrine psychosis, appeared in 13 cases among 700 treated during one period in Ceylon, 6 cases among many thousands treated in Kuala Lumpur and 4 cases in approximately 9,000 treatments in Malaya. Field concludes that the incidence of atabrine psychosis may tentatively be placed at less than one in a thousand cases treated. The incidence of mental symptoms during or subsequent to the administration of atabrine in the Western Hemisphere appears to have been at least equally small. There have been no reports of mental symptoms as a result of the administration of atabrine in prophylactic dosage. Confusional psychoses sometimes occur as a direct result of malarial infection, and some patients under treatment for malaria may have preexisting mental abnormality. Therefore it should not be assumed that every mental aberration following treatment with atabrine is necessarily due to atabrine. Atabrine is used extensively by the United States Army. Circular Letter 22, Office of the Surgeon General, War Department, Washington, D. C., Jan. 16, 1943, outlines the following optional methods of treatment for uncomplicated malaria:

1 Combined QAP treatment (method of choice)

(a) Quinine sulfate 0.64 Gm (10 grains) three times daily after meals for two or three days or until pyrexia is controlled. Then give

(b) Atabrine 0.1 Gm (1½ grains) three times daily after meals for five days. Then after two days without antimalarial medication give

(c) Plasmodium 0.01 Gm (1/100 grain) three times daily after meals for five days, except for the debilitated patient who should receive only two doses daily. (Discontinue if toxic symptoms occur. Never give atabrine and plasmodium concurrently.)

2 Atabrine-plasmodium treatment (May be used for simple Plasmodium vivax infections and in other infections when no quinine is available)

(a) Atabrine as described for seven days. Then after two days without antimalarial medication give plasmodium 0.01 Gm three times daily for five days, as described.

3 Quinine plasmodium treatment (Method when no atabrine is available)

(a) Quinine sulfate as described for seven days during the last five of which accompany each dose of quinine with plasmodium 0.01 Gm three times daily.

NOTE—Quinine sulfate tablets are more quickly effective if dissolved before being taken. Ten grains of quinine sulfate may be dissolved in 1 ounce of water which has been acidified by the addition of 10 minims of diluted sulfuric or hydrochloric acid (U. S. P.) or 2 Gm (30 grains) of citric acid.

The same circular letter outlines as drug prophylaxis or suppressive treatment of malaria the following methods:

Atabrine in doses of 0.4 Gm a week is recommended as the standard suppressive treatment of quinine daily. The atabrine should be taken 0.1 Gm twice a day on two non-successive days a week with water and immediately after meals. The prophylactic dosage of quinine is 5 to 10 grains daily after the evening meal. Under present conditions quinine prophylaxis is to be used only if a man cannot tolerate atabrine.

ROLE OF AMINO ACIDS IN HUMAN NUTRITION

Present knowledge of the role of the various amino acids in nutrition is based in large part on observations on the white rat.¹ As one of a series of studies designed to determine the amino acid requirements of the human species, Rose and his colleagues² employed two healthy young men to serve as the subjects for preliminary tests. They found that nitrogen equilibrium in these subjects could be readily maintained by diets containing only ten amino acids. This fact demonstrates that the twelve acids previously shown to be dispensable for rats and dogs are also nonessential for man. At the expiration of the 'fore period' of eight days during which these preliminary tests were made, valine was removed from the diet and the other amino acids were increased to provide a sufficient nitrogen content. The effects of this change were profound: immediately each of the two subjects manifested a negative nitrogen balance. On the fourth day the nitrogen output exceeded the intake by 2.19 and 2.91 Gm respectively. Valine was then returned to the food and was followed quickly by the reestablishment of positive nitrogen balances. After six days on the complete diets, methionine was excluded from the food for a period of six days. Again the subjects lost more nitrogen than was ingested, although the negative balances were not so large as after valine deprivation. Immediately after the readministration of methionine positive balances were restored. These observations demonstrate that the amino acids valine and methionine are indispensable dietary components for man; deficiencies of these amino acids create additional "deficiency diseases."

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

SCIENTIFIC WORK IN LENINGRAD

PROF K KERCHIEV

Supplied by Soviet Scientists' Antifascist Committee

A rather large volume entitled "Works of the Institute for Advanced Training of Medical Practitioners" has just been published. The volume deals with sixty-eight researches carried out during the first year of the war. In September 1941 the battle front was approaching the gates of Leningrad. The streets, houses and hospitals were being bombed and shelled, the city's food supply was cut off by blockade, the hospitals were deprived of electricity, dressings, equipment and medicines, but still the city did not surrender. In spite of incessant air attacks the doctors continued to treat the sick and the wounded and at the same time made numerous attempts to discover new medicines to replace those usually employed but then unobtainable.

The problem of healing wounds was the chief concern of the medical men in Leningrad. The members of the institute among them the surgeon N. Petrov introduced various new methods for the treatment of wounds, they gave considerable attention to a study of roentgenographic methods of locating shell and bomb fragments, and bullets lodged in the bodies of the wounded. A number of research projects were carried on in connection with serious wounds of the face and jaws. By discovering methods of healing such wounds Leningrad physicians saved the lives of thousands of

fighters. The cure of scurvy and other hypovitaminoses due to the scarcity of food was another subject taken up by the institute.

When motor transportation was established during the winter of 1941-1942 across Lake Ladoga and supplies of food were delivered to the city of Leningrad it was possible in many cases, with the help of physicians, to relieve the effects of undernourishment. The cure of frostbite, the restoration of peripheral nerves and other problems in neurosurgery were studied by Leningrad physicians to find better ways for saving the lives of the fighters. "The interdependence of science and practice has never been felt to such an extent as during the trying months of 1941-1942" say the authors of this volume. The suggestions of doctors were immediately put into effect and served as a "stimulus to continue and widen the field of research." The efforts of these sixty-eight scientific research workers of Leningrad Institute represent heroic exploits carried out under harrowing conditions in a besieged city within range of the enemy guns. These reports prove that it is possible to continue scientific work under the most difficult conditions if the research is of sufficient importance to one's home land and vital to the needs of the army.

ARMY

CLASS OF MEDICAL INSPECTORS

A class composed of forty-two officers of the medical corps graduated at the Medical Field Service School at Carlisle Barracks, Pa., February 6, after a month's training in the course for medical inspectors, whose duties are to supervise sanitation and medical preventive measures in army camps and to make recommendations for the correction of insanitary conditions. Twenty-five members of this class had previously graduated at Carlisle Barracks from the basic courses for officers. Another class of medical inspectors, numbering about fifty medical officers, started on February 15.

MAJOR FLICKINGER AWARDED DISTINGUISHED FLYING CROSS

Major Don D. Flickinger, a graduate of Stanford University Medical School, was awarded the Distinguished Flying Cross in 1941 for his work as flight surgeon on the pioneer trip of a squadron of B17's to the Philippines. Major Flickinger has now returned from the Pacific island theater and has been appointed flight surgeon at the Mather Field, Sacramento, an advanced flying and navigation school. He has developed a rescue method for pilots forced down at sea whereby they become visible for long distances when they land in the water. Major Flickinger spent many hours in the water in developing this device.

CAPTAIN GAMSO AWARDED SILVER STAR

The War Department announced on February 14 the award of the Silver Star for gallantry in action in New Guinea to Capt. Rafael R. Gamso of Brooklyn. Captain Gamso attended the public schools of Dallas, Texas, graduated in medicine at Baylor University College of Medicine in 1936 and interned at Cumberland Hospital, Brooklyn. He went into the service on Jan. 29, 1941 and went overseas on April 1, 1942. Dr. Gamso is 31 years of age.

DR. SUTTER CITED FOR BRAVERY

Dr. LeRoy M. Sutter of Orlando, Fla., has been cited in orders of commendation for bravery under fire and for service beyond the call of duty in North Africa, the newspapers have reported. Prior to entering the Army in the spring of 1942, Dr. Sutter was on the staff of the Florida Sanitarium and Hospital in Orlando.

DOCTORS IN KHAKI

Camera men, technicians and stage director Herman Shumlin arrived at the Medical Field Service School, Carlisle Barracks, Pa., February 13, to begin the production of a movie entitled "Doctors in Khaki" for the Office of War Information for release to civilian audiences. The script, which was prepared by the well known team Mr. and Mrs. Albert Hackett, deals

with the advanced training methods developed at Carlisle Barracks for adapting the talent of medical men to combat duty. The cast will comprise the officers actually on duty at Carlisle Barracks and the officers attending classes there. Thus medical officers from all parts of the country may be seen in the picture at work preparing to save lives on far flung battle fields. The picture, which has been designed to show the training of the nation's doctors of medicine for field duty, will follow the home town physician throughout his period of study at the field service school. It will be a public feature short, released soon. Mr Shumlin and Mr and Mrs Hackett are giving their time without pay in the interest of the war effort.

NAVY

PROMOTIONS FOR NAVY NURSES

Recent regulations authorized the promotion of Miss Sue S Dauser, superintendent of the Navy Nurse Corps, to the relative rank of captain and authorized higher relative ranks for two assistant superintendents and four directors of the Nurse Corps, which now comprises 3,200 nurses. Miss Dauser, who has just been reappointed for a second four year term as superintendent of the Navy Nurse Corps, has been in the naval service since November 1917.

The two assistant superintendents of nurses who were promoted from the relative rank of lieutenant to that of commander are Loretta Lambert of Claysville Pa, and Mary D Towse of Pittsburgh and the four directors promoted from lieutenant to lieutenant commander are Helen M Bunte of McSherrytown, Pa, Elizabeth M O'Brien of San Francisco, Myrtle R Carver

ARMY PERSONALS
Lieut Col George H Ham of Culver City, Calif, has been appointed surgeon at the Army Air Corps Base, Kew Field. Miss Lieutenant Colonel Ham in 1930 went in training at the School of Aviation Medicine at Brookfield Texas, then returned to the civil practice of his profession in Culver City until Dec 15, 1939, when he was called to active duty and assigned to March Field, Calif, since then he has served also at Glendale and at Mather Field, Calif, where he organized a 200 bed hospital, and as the surgeon of the Ferry Command with headquarters in Washington, D C.

of Raleigh, N C, and Anna G Keating of Philadelphia. A number of other nurses were promoted from the relative rank of lieutenant (j g) to that of lieutenant.

KITS FOR SUBMARINE CHASERS

The Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York City, shipped on February 5 thirteen special portable emergency medical kits to a submarine chaser training center in the South and announced a drive for \$25,000 to furnish similar medical kits to numerous submarine chasers in the U S Navy. The kits, made of fiber board with metal edges, will fit in a square foot of space. The kits thus furnished contained tourniquet, bandages, forceps, scalpel, gauze pads and ointments and medicines for the emergency treatment of burns and other injuries. In view of their size, submarine chasers are not usually staffed by medical officers.

CIVILIAN DEFENSE

ORGANIZATION OF STATE GAS SPECIALIST SCHOOLS

The Office of Civilian Defense, Washington, D C, issued on February 9 Operations Letter No 109, which reads as follows:

The training of gas officers and gas reconnaissance agents, as set forth in Operations Letter No 91, requires the establishment of state gas specialist schools at universities or technical schools to supplement the gas specialist courses given at War Department civilian protection schools. Most gas reconnaissance officers and many senior gas officers will be unable to attend War Department civilian protection schools because of the limited enrolment of these schools and the time and expense involved in attendance.

It is recommended that state schools for gas specialists be established now in regions I, II, III and IX and later in the other regions. The regional sanitary engineer and gas officer should consult with the state director or coordinator of Civilian Defense and the state gas consultant in selecting the schools which will be asked to cooperate in establishing the gas specialist courses. Availability of rooming and feeding facilities for students should be considered.

The selected schools should be asked to provide teaching personnel for technical subjects, classrooms and laboratory facilities. The state gas consultant should be responsible for (1) arranging schedules of instruction with the school authorities, (2) arranging all field administrative matters such as recruiting students and arranging for demonstrations, (3) giving the instruction on organization of the state gas program.

Sanitary engineers and gas officers in these regions should arrange for the attendance at War Department civilian protection schools of one or two representatives of each of the selected universities. Candidates should be members of the faculty who are willing to assist the state defense council in organizing the course and in providing the instruction.

Tentative plans for the state gas specialist schools call for a three day course with emphasis on gas identification and reconnaissance. The gas protection section of the medical division will assist in arranging the procurement of equipment for demonstration purposes. Whenever possible, arrangements will be

made for the attendance of a small military unit to demonstrate materials which cannot be placed in the hands of civilian instructors. A course outline and instructor's manual are being prepared for use in these schools.

CIVILIAN DEFENSE PERSONALS

Dr Jack Masur, executive director of Lebanon Hospital, New York, has been commissioned passed assistant surgeon in the U S Public Health Service and assigned to the Medical Division of the Office of Civilian Defense as hospital administration specialist to succeed Mr Henry N Hooper, who resigned last October to enter military service. Dr Masur graduated from Cornell University Medical College, New York, served an internship at Bellevue Hospital and had a residency at Montefiore Hospital, New York, from which hospital he was a traveling fellow to the medical service of Prof I Snapper in Amsterdam, Netherlands.

Dr Abraham N Franzblau, professor of religious education and pastoral psychology at Hebrew Union College, Cincinnati, has been commissioned a passed assistant surgeon in the U S Public Health Service and has been appointed to the Medical Division of the Office of Civilian Defense, Washington, D C. Dr Franzblau received his Ph D in 1934 in psychology and education and graduated from the University of Cincinnati College of Medicine in 1937, since which time he has been a fellow in research on diabetes and myasthenia gravis at the Jewish Hospital in Cincinnati.

Dr Dudley A Reekie, Boston regional medical officer of the first civilian defense region has been assigned acting chief of the Field Casualty Section of the Office of Civilian Defense in the absence of Dr Leonard A Scheele, who is assigned to special duty. Dr A William Reggio, Boston, state chief of Emergency Medical Service, is acting regional medical officer.

Dr Lloyd H Gaston, Baltimore, assistant regional medical officer in the third civilian defense region, has been transferred to Chicago to become assistant regional medical officer, associated with Dr John S Coulter regional medical officer for the sixth region.

MISCELLANEOUS

VICTORY STUDENT NURSE
CORPS PROPOSED

Mr Paul A McNutt federal security administrator is considering a proposal by the Health and Medical Committee of the Office of Defense Health and Welfare Services intended to help meet the critical shortage of nurses. The proposal includes provisions for stipends for student nurses the use of a portion of the senior students in government and military hospitals and distinct insignia for the corps also the condensing of the training period for student nurses from thirty six to thirty or twenty four months. Maintenance would be provided throughout the training period and on graduation, nurses either would enter the armed forces with the rank and pay of second lieutenant or ensign or be assigned to governmental or civilian nursing services essential to the war effort. Any student enrolled in a participating school of nursing after Jan 1 1941 would be eligible to volunteer for the Victory Student Nurse Corps. In connection with this proposal, Dr Thomas Parran, Surgeon General of the U S Public Health Service, said that future quotas of the army and navy cannot be made from the current nurse supply without a threatened collapse of nursing care for the civilian population.

PERUVIAN PHYSICIAN VISITS
PLASMA LABORATORIES

Dr Jorge Avendano, director of the clinical laboratories of the Hospital de Obreros Lima Peru is visiting a group of Eastern hospitals under the auspices of the Office of the Coordinator of Inter-American Affairs and the Office of Civilian Defense to study the organization of blood and plasma banks and the preparation of both liquid and dried plasma. Arrangements for Dr Avendano's visit to the United States were made through the Division of Health and Sanitation of the Coordinator's Office, and his itinerary of hospitals was arranged by the Medical Division Office of Civilian Defense. The Medical Division in cooperation with the U S Public Health Service, is assisting about one hundred and fifty hospitals in target areas to establish blood and plasma banks in order that adequate reserves of plasma may be available for the treatment of casualties caused by enemy action or any major wartime disaster. Dr Avendano is spending two weeks at the Bryn Mawr Hospital Bryn Mawr Pa, and several days each at Albany Hospital Albany N Y Strong Memorial Hospital, Rochester, N Y, and Syracuse University Hospital, Syracuse N Y.

MILITARY CROSS AWARDED TO
PHYSICIAN PARACHUTIST

Lieut Charles Granville Rob of the Royal Air Force medical corps has been awarded the Military Cross, according to a dispatch from London, February 11. He is said to be the first 'parachuting doctor' to gain a military award. After a flight of 350 miles and a parachute drop he performed one hundred and forty surgical operations, under extremely difficult conditions and bombings in Tunisia. After performing many operations in one day, he is said to have given a pint of his own blood when the supplies of blood ran short.

PERSONALS

Miss Marion W Sheahan of Albany, N Y director of the Division of Public Health Nursing of the New York State Department of Health, has been appointed chairman of the Subcommittee on Nursing Health and Medical Committee, Office of Defense Health and Welfare Services Washington, D C. The purpose of this subcommittee is to make over-all studies of nursing needs and recommend methods of meeting them and to coordinate all phases of the nation's wartime nursing problems. Miss Jean Henderson, public relations consultant of the Florida State Department of Health has been appointed information consultant to the Subcommittee on Nursing of the Health and Medical Committee, Office of Defense Health and Welfare Services Washington D C.

PUBLIC HEALTH UNDER HITLER

NPD of Dec 14, 1942 states that following an invitation of the reich minister for the occupied eastern territories Dr Conti, the reich health leader, is spending several days in the reich commissariat Ostland. Dr Conti intends to visit the authorities and institutions of the German health services with the reich commissioner and the commissioner generals in Riga, Tallinn and Kaunas, so that he can acquaint himself personally and on the spot with the work of reconstruction carried out so far.

In order to ensure supplies of medicines and dressings for the Ostland, the 'Pharm Ost-Ltd' has been set up in connection with the reich ministry for the occupied eastern territories.

An order made by the reich commissar for the Ostland announces the establishment of "chambers of health" in Estonia, Latvia and Lithuania. These chambers of health unite the following professions of the health services: physicians and their assistants, dentists and their assistants, pharmacists and their assistants, midwives and nurses.

NDZ of Dec 3 1942 says that cancer is one of the diseases which, next to tuberculosis, is not yet being properly dealt with. An average of 150,000 people per annum die of cancer in Germany and 500,000 people suffer from cancer. The fight against cancer has now been put on a new basis by the formation of a reich committee for combating cancer. In the periodical *Gesundheitsführung* the deputy president of the committee, Dr Ramm, describes the task of the committee as consisting in issuing directives for the fight against cancer and for its prevention, diagnosis and cure, holding a census of the number of sufferers from cancer and investigating the course of the disease, promoting the specialized training of doctors and finally conducting a large scale campaign against public ignorance.

It is intended to set up an advice center in every kreis of the reich. All facilities for diagnosis and cure are to be available in every gau. Parallel with the efforts to insure an early diagnosis of the disease, the reich health directorate will take steps to improve preventive measures. These will have to extend for instance, to matrimonial advice, to regulating the manner of living and insuring a natural diet. In addition the winter demands that all women above the age of 30 and men roughly from the age of 40 to 45 should periodically be examined for prophylactic purposes. He does not, however, advocate that this examination should be compulsory but expects that by appealing to the sense of duty of the more enlightened parts of the population it will be possible to carry out these measures on a voluntary basis.

The *Frankfurter Zeitung* of Dec 2, 1942 reports a decree by Koch, the gauleiter of East Prussia, saying that the schools in East Prussia must devote at least two lessons a month to teaching their pupils personal hygiene and decent manners. Koch orders that at least once a week every form master must ascertain whether every child has a clean handkerchief, whether the hands, face and clothes are clean, the hair cut and the boots kept in proper condition. He must pay special attention to cleanliness of the hands ears and scalp. He must examine whether the child's clothes are whole clean and properly aired. He must examine the condition of the children's schoolbooks and at the same time instruct them in the principles of personal hygiene. He must constantly watch the children's state of health and immediately report anything unusual to the parents and the school doctor. In particular he must see to it that the children do not run about in damp clothes before lessons if the weather is bad but must make them change their boots and order them to exercise to get warm. He must make sure that the classrooms are properly aired and that the children regularly get an uncooked breakfast.

According to *Svenska Dagbladet*, Stockholm, January 14, the rumors which circulated in Norway about the death of Germans during a march across the mountains has been confirmed. The German troops, consisting of some infantry and two bicycle companies, were traveling 150 kilometers across Saltfjellet in Nordland County to Fauske. Because of the snow and cold weather the soldiers covered only 30 kilometers on the first day and spent the night in cold barracks. The men were insufficiently clad and 6 froze to death and about 100 were frost bitten.

ORGANIZATION SECTION

OFFICIAL NOTES

NATIONAL CONFERENCE ON PLANNING POSTWAR MEDICAL SERVICES

On March 15 at the Waldorf-Astoria, New York, will be held the National Conference on Planning for War and Postwar Medical Services, under the auspices of the Carlos Finlay Institute of the Americas. Cooperating in holding the conference are the American Medical Association, the American College of Physicians, the American College of Surgeons, the American Drug Manufacturers Association, the American Hospital Association, the American Pharmaceutical Manufacturers Association, the American Pharmaceutical Association, the American Surgical Trade Association, the Wholesale Surgical Trade Association and the National Physicians Committee for the Extension of Medical Service.

The announcement of the conference explains that "There is an urgent need to mobilize the leaders of the medical profession and of the supporting industries for planning of postwar medical services."

The Carlos Finlay Institute of the Americas was organized a year ago¹ in Havana, Cuba, to foster scientific interchange and good will among the medical professions of the Latin American countries. Mr. Basil O'Connor, New York, president of the National Foundation for Infantile Paralysis, is president of the institute. Directors are Dr. Morris Fishbein, Dr. Morton Kahn, Lieut. Col. Thomas Mackie, M. C., U. S. Army, Dr. Edgar Mayer, Mr. O'Connor, and Dr. James E. Paullin. The institute was incorporated in New York state in December 1942. Representing the cooperating organizations in arranging the conference are one hundred and seventeen leaders in medical and allied fields.

The morning and afternoon sessions of the conference will be open to all interested physicians, but the evening session will be limited to an invitation list. All sessions will be held at the Waldorf-Astoria.

Presiding at the morning session which will start at 10 o'clock, will be Dr. James E. Paullin, Atlanta, Ga., president of the American College of Physicians and President Elect of the American Medical Association. Speakers and their subjects will be: Lieutenant Colonel Mackie, executive officer, Tropical and Military Medicine, Army Medical School, Washington, D. C., "War and the Migration of Tropical Diseases"; Dr. Thomas Francis Jr., professor, Department of Epidemiology, University of Michigan School of Public Health, Ann Arbor, Mich., "Epidemiology of Influenza"; Dr. Lowell T. Coggeshall, University of Michigan School of Public Health, "Malaria—A World Menace," and Dr. John B. Youmans, associate professor of medicine, Vanderbilt University School of Medicine, Nashville, Tenn., "Nutritional Diseases as a Postwar Problem."

At the afternoon session which will convene at 2:30, Brig. Gen. Fred Rankin, M. C., U. S. Army, President of the American Medical Association, will preside. Speakers and their subjects will be: Edward C. Elliott, Ph.D., LL.D., president, Purdue University, member War Manpower Commission, Washington, D. C., "Postwar Needs for Medical and Other Trained Personnel"; Col. C. F. Shook, M. C., U. S. Army, Washington, D. C., "Postwar Channeling of Drugs and Medical Supplies"; and A. R. Dochez, Rockefeller Institute for Medical Research, "Trends in Scientific Research."

The evening session will be a dinner meeting, starting at 7 o'clock. Mr. John G. Searle, president of the American Drug Manufacturers Association, will introduce Mr. O'Connor, who will preside as toastmaster.

Mr. Nelson A. Rockefeller, coordinator of Inter-American Affairs, Washington, D. C., will speak on "The Health Problems of the Americas."

Mr. Frederick P. Keppel, director, Equitable Life Assurance Society of the United States and of the U. S. Guaranty Trust

Company, New York, will speak on "Health—A World Problem."

Mr. Norman Davis of the American Red Cross, Washington, D. C., will tell of "The Place of the American Red Cross in Medical Rehabilitation."

Dr. Fishbein, Editor of THE JOURNAL, will speak on "American Medicine's Contribution to the Postwar World."

REPORT OF MEETINGS OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS, HELD IN CHICAGO, FEB. 13 AND 14, 1943

The Liaison Committee of the Council on Medical Education and Hospitals and the Association of American Medical Colleges met Saturday evening, February 13, at the Palmer House in Chicago.

The Council approved the basic pattern of the army specialized training program for premedical students as presented by Col. F. M. Pitts of the Army Specialized Training Division, Headquarters Services of Supply, Washington, D. C.

Inter-American relationships in the field of graduate medical education were discussed.

In view of the war demand, the Council withdrew objection to medical schools recorded as on a probationary status on the list of approved medical schools maintained by the Council adopting accelerated programs. This action was taken with the understanding that the responsibility for such programs and the maintenance of standards should be definitely accepted by these schools.

The Council considered reports on eight medical schools visited by the Secretary.

The probationary status of the University of Georgia School of Medicine on the list of approved medical schools maintained by the Council was removed, thus restoring this school to unconditioned approval.

Consideration was given to suggested programs for the development of two schools of the basic medical sciences into complete medical schools.

The Council appointed a committee to confer with representatives of the American Hospital Association and the Association of American Medical Colleges in regard to the general problem of hospital internships.

Attention was given to the problem of the Council meeting its responsibilities during the war period with a more or less depleted staff.

The following internships and residencies were approved by the Council:

Hospitals Approved for Internships

San Joaquin General Hospital, French Camp, Calif.
St. Joseph's Hospital, Joliet, Ill.
Jennie Edmundson Memorial Hospital, Council Bluffs, Iowa
Nazareth Hospital, Philadelphia
Alexandria Hospital, Alexandria, Va.

Approved Residencies

Medicine
St. John's Hospital, St. Louis
Mixed
Mercy Hospital, Hamilton, Ohio
All Saints Episcopal Hospital, North Worth, Texas
Neurosurgery
University of Chicago, Chicago
Pediatrics
General Hospital of Fresno County, Fresno, Calif.
Surgery
St. Francis Hospital, Wichita, Kan.
St. John's Hospital, St. Louis
Bronx Hospital, New York City
St. Paul's Hospital, Dallas, Texas
Mary Fletcher Hospital, Burlington, Vt.
Tuberculosis
Hospital for Incipient Tuberculosis, Ray Brook, N. Y.
Schenectady County Tuberculosis Hospital, Schenectady, N. Y.
(Glenridge Sanatorium)

Additional residencies were reviewed by the Council, but final action is being held in abeyance pending approval by the

¹ Finlay Institute of the Americas, J. A. M. A. 118:230 (Jan. 17) 1942.

respective specialty boards with which the Council has a program for concurrent approval of residencies

The following technical schools were approved by the Council

Schools for Clinical Laboratory Technicians Approved

St Joseph's Hospital Denver
New Britain General Hospital New Britain Conn
Waterbury Hospital Waterbury Conn
Methodist Hospital of Central Illinois Peoria Ill
Rockford Memorial Hospital, Rockford Ill
St Anthony's Hospital Rockford Ill
Maine General Hospital Portland Maine
St Joseph's Hospital Baltimore
Taunton State Hospital Taunton Mass
Tewksbury State Hospital and Infirmary Tewksbury Mass
Port Huron Hospital Port Huron Mich
Northwestern Hospital Minneapolis
Bishop Clarkson Memorial Hospital Omaha
Newark Beth Israel Hospital Newark N J
Prospect Heights Hospital Brooklyn
Meadowbrook Hospital Hempstead N Y
Beth Israel Hospital New York
St Luke's Hospital New York
Grasslands Hospital Valhalla N Y
St Luke's Hospital Bethlehem Pa
Williamsport Hospital Williamsport Pa
Mount Sinai Hospital Milwaukee

School for Physical Therapy Technicians Approved
Graduate Hospital of the University of Pennsylvania Philadelphia

School for Occupational Therapy Technicians Approved

New York University, New York

Plans were formulated for revising the "Essentials of an Acceptable School for Physical Therapy Technicians" and the "Essentials of an Acceptable School of Occupational Therapy," as well as the preparation of minimum "Essentials of an Acceptable School for Medical Record Librarians"

Consideration was given to a progress report of the Council's cooperation with the American Medical Association's Committee on Health Resorts involving the inspection of health resorts by the staff of the Council

Other items were discussed or are under consideration

The Council met with the Advisory Board for Medical Specialties on Sunday evening February 14

H G WRISKOTTEN, Secretary

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—S 739 and H R 1912 have been respectively reported to the Senate and House with recommendation that they pass. These bills are identical in phraseology and provide that during the present war and for six months thereafter personnel of all components of the Army of the United States may be detailed as students at technical, professional and other educational institutions or as students, observers or investigators at industrial plants, hospitals and other places. H R 1975 has passed the House making certain deficiency appropriations. The House Committee on Appropriations refused to include in the bill an authorization of \$1,200,000 for the Children's Bureau to utilize in making grants for emergency maternity and infant care for wives and infants of certain enlisted men. An effort to have inserted in the bill this authorization on the floor of the House was unsuccessful.

Bills Introduced—S J Res 34, introduced, by request, by Senator Russell, Georgia, proposes to establish the first week in October of each year as "National Employ the Physically Handicapped Week." H R 1879, introduced by Representative Bennett, Michigan, proposes a federal appropriation of \$700,000 to construct a veterans' hospital in the Upper Peninsula of Michigan to accommodate 150 bed patients. S 785, introduced by Senator Walsh, Massachusetts, and H R 1936 introduced by Representative Maas, Minnesota, would authorize an appropriation of \$2,000,000 to provide for the expansion of facilities for hospitalization of dependents of Naval and Marine Corps personnel. H R 1956, introduced by Representative Sadowski, Michigan, provides that every person in the military or naval forces of the United States, including the Women's Army Auxiliary Corps, the Women's Reserve of the Naval Reserve, the Women's Reserve of the Coast Guard and the Women's Reserve of the Marine Corps shall be exempt from all taxes imposed by the United States on income. S 778, introduced by Senator Stewart, Tennessee, proposes to authorize an appropriation of such sums as may be necessary to enable each state to furnish financial assistance to needy individuals who are permanently and totally disabled. H R 1990, introduced by Representative Hoch, Pennsylvania, proposes to establish a Chiropody Corps in the Medical Corps of the Army and to establish within the Medical Corps a Chiropody Reserve Corps in accordance with the provisions of the National Defense Act with rank, promotion, pay and allowance equivalent to that of the Dental Corps.

STATE MEDICAL LEGISLATION

Arizona

Bill Introduced—H 165, to amend the workmen's compensation act, proposes to authorize an injured employee to elect to be attended by a licensed chiropractor and thereafter to be entitled to the benefits of the workmen's compensation act to

the same extent as if attended by a licensed practitioner of medicine and surgery.

Arkansas

Bill Introduced—S 162, to amend the medical practice act, proposes to repeal the provisions providing for the annual registration of resident and nonresident practitioners holding licenses issued by the State Medical Board of the Arkansas Medical Society.

Colorado

Bills Introduced—H 112 proposes to exempt physicians from annually registering their certificates during the term of active duty with the Army, Navy, Marine Corps, Coast Guard, State Militia, Red Cross or in the military service of any of the Allies of the United States. H 199, to amend the chiropractic law, proposes to require chiropractors, at the time of the annual renewal of their licenses, to present proof that they have attended at least three days of a scientific clinic, forum or educational study approved by the Colorado state board of chiropractic examiners.

Delaware

Bills Passed—S 38 passed the senate, February 15. It proposes to authorize the medical council of Delaware to issue temporary emergency certificates to physicians licensed outside the state. S 41 passed the senate, February 16. To amend the medical practice act, it proposes to exempt therefrom the treatment of human ills by prayer or spiritual means in accordance with the tenets of any well recognized religious denomination.

Georgia

Bill Introduced—S 85, to amend the uniform narcotic act, proposes, among other things, to exempt from the operation of the act the administering, dispensing and selling at retail of certain attenuated narcotic preparations.

Bill Passed—H 136 passed the house, February 22. It proposes to require all licensed physicians attending a pregnant woman to take a sample of blood within thirty days of the first examination and to submit such sample to an approved laboratory for a serologic test for syphilis.

Indiana

Bill Passed—S 135 passed the senate, February 12. It proposes to prohibit school authorities from employing food handlers who are addicted to drugs or who have tuberculosis or syphilis in an infectious stage and to require all school employees to undergo a physical examination for tuberculosis at least once every three years by a duly licensed doctor of medicine.

Iowa

Bills Introduced—S 291, to amend the workmen's compensation act, proposes to provide for the payment of workmen's compensation benefits for any disability due to a disease con-

tracted by the employee in connection with the work under the employment S 295 proposes that, in the management of a hospital established by a county, city or town with funds received by gifts, no discrimination shall be made against the practitioners of any school of medicine recognized by the laws of the state, each patient shall have the right to employ at his expense any physician of his own choice, any such physician shall have the exclusive charge of the care and treatment of the patient in such hospital, and the attending nurses shall be subject to the direction of such physician S 299, to amend the law relating to the licensing of maternity hospitals, proposes to redefine "maternity hospital" so as to include any general hospital

Bill Passed—S 82 passed the senate, February 18 To amend the income tax law, it proposes to authorize taxpayers to deduct expenses for the medical care of the taxpayer, and the term "medical care" is defined as amounts paid for the diagnosis, cure, mitigation, treatment or prevention of disease, or for the purpose of affecting any structure or function of the body A senate amendment of February 18 proposed to allow also a deduction for treatment or nursing as prescribed by a well recognized church or religious denomination in a hospital or sanatorium conducted by such church or denomination

Kansas

Bills Introduced—S 227 proposes to provide workmen's compensation for certain occupational disease H 91, previously referred to, was so amended in the house on February 11 as to authorize the state board of osteopathic examination and registration to grant temporary licenses to osteopaths licensed outside the state during the present war emergency

Maryland

Bill Introduced—H 276 proposes to require any physician who knows, or has reason to believe or suspect, that any person under his professional care is infected with syphilis, gonorrhea or any other venereal disease to give immediate notice thereof in writing to the state board of health

Bill Passed—S 84 passed the house, February 16 It proposes to amend the medical practice act by eliminating the proviso that no two courses of medical lectures shall be either begun or completed within the same calendar year This amendment is for the purpose of enabling graduates of accelerated medical courses to obtain licensure in Maryland

Bill Enacted—S 47 has become chapter 23 of the Laws of 1943 It increases from one to two dollars the fee which a physician may receive for executing a certificate under the employment law

Massachusetts

Bills Introduced—H 723 proposes to require a chartered hospital to accept any patient when so requested by a physician licensed to practice medicine in the state H 868 proposes to require an operating surgeon, after the removal of any limb or organ, to deliver a written statement of explanation to the patient or the patient's husband, wife or relatives advising the nature of the operation which he performed and giving reasons for considering such operation necessary H 869 proposes to require every qualified physician to submit, at least twice a year, to a blood test for syphilis and gonorrhea

Bill Passed—H 1013 passed the house on February 16 and the senate on February 23 It proposes to add the requirement that physicians report all cases of wounds from a BB gun to the commissioner of public safety and to the police authorities

Minnesota

Bill Passed—H 273 passed the house, February 11 It proposes that physicians in the armed forces shall not be required to renew their annual licenses during the term of such service and shall be exempt from payment of all renewal fees

Missouri

Bill Introduced—H 214 proposes to exempt physicians from renewing their licenses annually during the term of their military service

Montana

Bills Passed—S 63 passed the senate on February 15 and the house on February 22 It proposes to authorize certain institutions of higher learning in Montana to obtain custody of unclaimed human bodies for use in the teaching and demonstration of anatomic science by professional instructors S 97 passed the house, February 22 It proposes to relieve physicians in the military service of the United States from paying annual license fees during the period of such service H 118 passed the house, February 18 To amend the medical practice act, it proposes to authorize the board of medical examiners to prescribe and enforce reciprocity requirements current with changes in standards of the practice of medicine and surgery

Nevada

Bill Introduced—A 114 proposes to define the term "to practice as an osteopathic physician" to mean the right to practice the art or science of healing limited to the manipulation of the bones and by other manual manipulations intended to restore the deranged mechanism of the human body, provided that any license granted under this proposal shall not give the holder thereof the right to practice obstetrics, nor to administer or prescribe drugs or medicine of any kind, nor to perform operations in surgery by the use of the knife or other instruments

New Hampshire

Bill Enacted—H 54 was approved, February 16 It provides for the establishment of a state department of health to take over the powers and duties of the state board of health

New Jersey

Bill Introduced—S 72, to amend the public school law, proposes to make immunization for diphtheria a mandatory rather than optional prerequisite to attendance at school and to make it mandatory for boards of education to provide the necessary equipment to immunize pupils whose parents, in the opinion of the board, are unable to meet the necessary expense

Bill Passed—A 94 passed the assembly, February 22 To amend the medical practice act, it proposes to exempt therefrom persons taking charge temporarily, on written permission of the board, of the practice of a lawfully qualified physician in the state, and further proposes conditions under which the board may grant such temporary permission

New Mexico

Bills Introduced—S 101 proposes to require the county school superintendent to see that all children in his county of school age under 8 years are immunized against diphtheria S 160 proposes that any person having a license to practice a profession in the state shall not be prejudiced by reason of having been drafted into the armed services but shall retain such license after release from such service

Bill Enacted—S 141 was approved, February 10 It provides that every physician who makes a diagnosis in or treats or prescribes for a case of venereal disease shall report such case immediately to the municipal or district health officer

New York

Bill Introduced—A 880 to amend the workmen's compensation act, proposes to authorize an injured employee, when care is required for an injury to his foot to be treated by a duly registered and licensed podiatrist of his own choosing

Bill Enacted—A 377 has become chapter 12 of the Laws of 1943 It authorizes a taxpayer to deduct, for income tax purposes, expenses paid or incurred during the taxable year for medical care of himself, his spouse or his dependents "Medical care" is defined as amounts paid or incurred for the diagnosis, cure, mitigation, treatment or prevention of disease or for the purpose of affecting any structure or function of the body or for maternity cases (including amounts paid for accident hospitalization or health insurance)

North Carolina

Bill Introduced—H 513, to amend the optometry law, proposes to authorize the state board of optometry to make use of the injunctive process in restraining the illegal practice of optometry

Bill Enacted—H 110 was ratified February 15. It authorizes state institutions for the care of the sick, feebleminded or insane to have performed on persons dying in such institutions a postmortem examination in the laboratories of incorporated medical schools after securing the written consent of the deceased persons husband or wife or next of kin

North Dakota

Bill Introduced—H 229 proposes a law for the organization and regulation of nonprofit hospital service plan corporations

Bill Passed—S 57 passed the senate February 19. It proposes the enactment of a uniform narcotic act

Oklahoma

Bill Introduced—S 129 proposes to authorize a person desiring employment, who has a physical defect which would impose on his employer a further or unusual hazard, to waive such physical defect on behalf of himself or his dependents and thus to forego any right to compensation for a personal injury which might be found to be attributable in a material degree to such physical defect

Oregon

Bill Introduced—S 248 proposes to require persons employed as food handlers to obtain at six month intervals a physician's certificate showing freedom from any infectious and contagious disease

Bills Passed—S 175 passed the senate February 16. It proposes to increase the annual registration fee from five to ten dollars for the period beginning Jan 1 1944. H 350 passed the house February 20. It proposes to authorize commissioned medical officers of the army to execute the required certificate necessary under the state premarital examination law

Bill Enacted—S 91 was approved February 19. It amends the osteopathic practice act by requiring osteopaths to register annually

Pennsylvania

Bills Passed—H 235 passed the house February 23. It proposes to authorize the state board of medical education and licensure to issue temporary certificates to physicians licensed in other states to authorize them to practice medicine and surgery in Pennsylvania for the duration of the present war and six months thereafter. H 236 passed the house, February 23. It proposes that for the duration of the war a minimum of nine months rather than one year internship shall constitute the necessary legal training to qualify for admission to examination for a license to practice medicine

Rhode Island

Bill Introduced—H 665 proposes to add rheumatic fever to the list of diseases which physicians must report to the state department of health

South Carolina

Bill Passed—S 17 passed the house, February 11. It proposes to eliminate from the medical practice act the requirement that the necessary four full courses of lectures of at least twenty-six weeks each must have been given in four different calendar years. The purpose of this proposal is to enable graduates of accelerated medical courses to obtain licensure in South Carolina

Tennessee

Bill Passed—H 420 passed the senate, February 9. It proposes to prohibit the sale or advertisement of articles used for the prevention of conception without a license issued by the state board of pharmacy except that physicians and medical practitioners regularly licensed to practice medicine or osteopathy in the state of Tennessee would not be prevented from prescribing such articles

Bills Enacted—H 39 has become chapter 107 of the Public Acts of 1943. It provides that hospitals and physicians called on to render first aid to persons suffering from any wound or other injury inflicted by means of a knife, pistol, gun or other deadly weapon or suffering from the effects of poison or suffocation shall report the same immediately to the chief of police. H 129 has become chapter 49 of the Public Acts of 1943. It provides for the creation of a state board of naturopathic examiners and defines naturopathy as the prevention, diagnosis and treatment of human injuries, ailments and diseases by means of any one or more of the psychological, physical or mechanical, chemical or material, forces or agencies of nature. The act shall not be construed, however, to permit or authorize any naturopathic physician licensed thereunder to perform any surgical work other than minor matters. H 903 has become chapter 117 of the Public Acts of 1943. It amends the workmen's compensation act to provide that an employer shall designate a group of three or more reputable physicians or surgeons from which the injured employee shall have the privilege of selecting the operating surgeon or the attending physician

Texas

Bills Introduced—S 114 and H 208 propose that the superintendent of a state hospital shall be a skilled physician authorized to practice medicine in Texas and of not less than five years' experience in the treatment of mental diseases. H 14, to amend the marriage law, proposes to require a male applicant for a marriage license to produce a certificate from a reputable licensed physician to show that he is free from all venereal diseases. H 65, to amend the marriage law, proposes that each applicant for a marriage license shall produce a certificate signed by a physician legally licensed to practice medicine in Texas showing such applicant to be free from syphilis and all other venereal diseases. Furthermore, the certifying physician would be required to remain in his office for a period of at least five years a detailed report of any laboratory test made

Utah

Bills Introduced—H 29 previously referred to, was amended in the senate on February 16 so as to require applicants for a license to practice naturopathy to have completed at least one year of internship in a hospital accredited by the American Hospital Association. H 160 proposes that any person with tuberculosis in a communicable form who fails to obey the tuberculosis laws or rules of the state board of health may be committed to a sanatorium on complaint by a health officer or a physician or surgeon licensed in the state of Utah

Vermont

Bills Introduced—S 16 proposes to authorize the institutionalization and treatment of persons who violate the criminal laws or who are guilty of gross immoral conduct because of mental deficiency, insanity or psychopathic personality. The latter term is defined as the existence in any person of such conditions of emotional instability or impulsiveness of behavior, lack of customary standards of good judgment, or failure to appreciate the consequences of his acts, as render him irresponsible for his conduct with respect to sexual or other criminal behavior and thereby dangerous to other persons. H 74, a substitute for H 50, to amend the law relating to the practice of medicine and osteopathy, proposes to authorize the examining board to make rules and regulations covering requirements for admission to practice medicine and surgery and osteopathy. H 151, to amend the premarital examination law, proposes to authorize the execution of the required certificate by an osteopath and by a member of the medical corps of the army, navy or public health service

Bill Passed—H 50 passed the house, February 12. It proposes to amend the medical practice act by repealing the section setting forth the requirements for admission to practice and to substitute therefor an authorization that the board shall make rules and regulations covering requirements for admission to practice medicine and surgery

Washington

Bills Introduced—S 181 proposes the creation of full time health districts within the state, provides for the establishment of district boards of health and the appointment of district health officers and prescribes their duties. S 214 proposes to require all persons employed in the preparation, serving or handling of food to be examined by the city health officer and to obtain a certificate showing freedom from any and all communicable diseases at least once every six months. The health officer is limited to a fee of two dollars for making such examination and certificate. S 222 proposes the creation of a state board of practical nurse examiners and defines practical nursing as the performing for compensation of such services as are necessary in the attendance on or the care of persons ill from chronic disease or convalescent, handicapped, mentally unbalanced or aged persons in homes, hospitals or institutions depending on or under the supervision of a regularly licensed and practicing physician. H 121 proposes to exempt charitable hospitals from taxation under certain conditions. H 245 proposes the creation of a cash sickness compensation fund and provides for the administration of such fund. H 256 proposes to require every elementary school from the sixth grade on and every high school or junior high school to institute and maintain as a regular part of its curriculum a course of study and practice of emergency first aid methods.

Bills Passed—S 218 has passed the senate. It proposes to authorize the director of licenses, during the present emergency, to grant temporary certificates to practice medicine and surgery to physicians duly licensed and qualified to practice under the laws of some other state and proposes that such temporary license shall be valid from the date of issuance until the next regular examination given by the board of examiners. H 41 passed the house, February 10. It proposes to authorize the establishment of emergency health and sanitation areas and sets forth certain regulations applicable to the state board of health in connection therewith. H 127 passed the house, February 12. It proposes to make it unlawful for any person to maintain or operate a maternity home without a license and defines maternity home as any place where women go to be delivered of children.

West Virginia

Bills Introduced—S 110 and H 181, to amend and reenact the law relating to mentally ill persons and mental defectives, propose, among other things, that the head of the newly created division of mental hygiene shall be a reputable physician and a graduate of an accredited medical school with at least five years' actual experience in the practice of his profession and

at least three years' actual experience as a physician in an institution for the care and treatment of mental illness. The proposals also provide for the licensing of all private institutions for the care, custody or treatment of mentally ill or mentally defective persons. H 264 to amend the medical practice act, proposes to exempt therefrom persons practicing Christian science.

Bills Passed—S 36 passed the senate February 24. It proposes the creation of a division of cancer control in the state department of health to administer provisions relating to the diagnosis, treatment and care of persons suffering from cancer, including the conduct of an educational program, the establishment of cancer clinics in general hospitals throughout the state and the furnishing of tissue diagnostic service to all patients. S 85 passed the senate, February 23. It proposes to authorize the board of governors of the West Virginia University to establish a four year medical course to be given either at the university or in part at other universities and medical colleges outside the state.

Wisconsin

Bill Passed—S 53 passed the senate February 17. It proposes to exempt members of the armed forces from being required to maintain a license to practice any profession within the state, proposes that this license shall be suspended during the active service of such persons, and proposes that it may be renewed within six months after such persons' discharge.

Wyoming

Bills Passed—H 58 passed the house, February 12. It proposes to prohibit the operation of a maternity hospital without a license issued by the state board of health. H 77 passed the house, February 12. It proposes regulations for the compulsory sterilization of inmates of certain state institutions if the inmates have been found to be insane, idiotic, imbecile, feebleminded or epileptic and the probable potential parents of socially inadequate offspring.

Bills Enacted—S 2 has become chapter 7 of the Laws of 1943. It amends the premarital examination law by (1) requiring the test to be made on females as well as males and (2) authorizing the execution of the certificate by any physician duly licensed under the laws of Wyoming and engaged in practice there. H 22 has become chapter 39 of the Laws of 1943. It amends the pharmacy law by providing that a hospital shall not be prohibited from keeping on hand and using professionally drugs, medicine or narcotics under the direction of physicians, dentists or veterinarians, even though there be no registered pharmacist present.

WOMAN'S AUXILIARY

New Jersey

A symposium on "Doctors' Wives in the War Effort and Home Community Service" made memorable the first of a new type of meeting of the Woman's Auxiliary to the Essex County Medical Society, Nov 23, 1942, at the Academy of Medicine. The program chairman, Mrs S Bernard Kaplan, introduced the uniformed members of the auxiliary prominently engaged in community activities. Mrs Henry C Barkhorn vice chairman of the Newark Red Cross chapter and chairman of the Woman's Division of the War Chest and Roll Call, presided. Mrs H Roy Van Ness discussed the many ways in which doctors' wives have aided in establishing community projects of help to the medical profession. Mrs A Elston Fink told how the wives of doctors at war could substitute for their absent husbands by listening to patients' woes and by entering actively in community projects. Mrs Arnold Kallen and Mrs Arthur Heyman, wives of two doctors who are with the Armed Forces, spoke of the spiritual satisfaction that they had found in their volunteer work as Nurses' Aides. Mrs Asher Yguda auxiliary president and wife of a naval officer, described life in a naval community and how she has organized the Civilian Defense of that community.

Virginia

The Norfolk auxiliary met on Dec 2, 1942 under the presidency of Mrs W E Butler. Dr A Brownley Hodges, Civilian Defense chief of emergency medical service, requested the assistance of the auxiliary members in distributing equipment for the casualty centers in Norfolk. The auxiliary is sponsoring the sale of war bonds and stamps at Ames and Brownley's Department Store every Monday, and to date stamps and bonds in the amount of \$27,000 have been sold. The members also serve at the sewing room of Red Cross headquarters every Friday and sponsor dances for service men at USO headquarters.

The December meeting of the Woman's Auxiliary to the Alexandria Medical Society was held at the "Laura Lee Candy House." Mrs Stanley King chairman of the Volunteer Special Service Committee of the Red Cross, discussed the training duties and requirements of the "Gray Ladies." Mrs Harrison Picot, chairman of the committee, with Mrs C E Arnette and Mrs C V Amole, made \$25 selling pansy plants. The proceeds will go to the buying of equipment for the Alexandria Hospital. The auxiliary donated the sum of \$160 to the Alexandria Laboratory for purchasing a microtone. A beautiful handmade quilt was raffled off and \$25 cleared.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ALABAMA

Personal—Dr William B Nelson, Bay Minette, health officer of Baldwin County, has been placed in charge of the health units at both Baldwin and Escambia counties.—Austin W Curtis Jr, for eight years assistant to the late George Washington Carver, DSc, director of the department of agricultural research at the Tuskegee Institute, has been named his successor.

State Committee Approves Establishment of Medical School—The establishment of a four year medical school in Alabama was assured on January 27 at a meeting of Gov. Chauncey Sparks Montgomery, with members of the state board of health and a special committee of the Medical Association of the State of Alabama appointed to promote the project. Tentative legislation has been drawn by the state medical association committee which would leave to a special commission to be appointed by the governor the matter of location, construction and equipment. The school will be known as the school of medicine of the University of Alabama and Dr William D Partlow, Tuscaloosa, chairman of the committee of the state medical association in a statement to the press, said that it will absorb the two year pre-medical course now offered at the University of Alabama. Birmingham has been suggested as the location for the two years advanced training. Establishment of the school has been endorsed by the state medical association, the state board of health and every county medical society in the state. Members of the committee of the state medical association promoting the project include Dr Partlow, chairman; Drs Edwin V Caldwell, Huntsville, James P Collier, Tuscaloosa, Samuel A Gordon, Marion, Samuel L Ledbetter, Jr, Birmingham, Burton F Austin, Montgomery, state health officer, John H Blue, Montgomery, Emmett B Frazer, Mobile, Paul P Salter, Eufaula, and Audiss M Walker, Tuscaloosa.

CALIFORNIA

Civil Service Examination for Intern—The Los Angeles County Civil Service Commission announces that applications for the position of intern are being accepted until April 15. There will be no written test. Candidates will be rated on their professional training and experience and their aptitude and personal suitability for internship as evidenced by investigation or interview. All candidates must be citizens of the United States who have completed a medical course at an approved medical school in the United States or Canada within five years prior to April 15 or who will have completed the course prior to July 1, 1944. Applications may be secured from the dean of any of the accredited medical schools or full information may be obtained by writing directly to the Los Angeles County Civil Service Commission, Room 102, Hall of Records, 220 North Broadway, Los Angeles.

Memorial to Eric Liljencrantz—The Hewlett Club of Stanford University School of Medicine, San Francisco recently established the "Eric Liljencrantz Memorial Collection on Aviation Medicine" in the Lane Medical Library in honor of the first member of the faculty to lose his life in the present war. Dr Liljencrantz, a commander in the medical corps of the U S Naval Reserve, was killed in an airplane accident while at sea near the naval air station at Pensacola, Fla., Nov. 5, 1942. He had been granted a leave of absence at Stanford where he was assistant professor of medicine (radiology), to carry out an assignment with the Bureau of Aeronautics in the Navy Department. The *Stanford Medical Bulletin* announced that any contributions to the memorial may be sent either to Dr Loren R Chandler, dean of the medical school or to Lane Medical Library.

Neurologic Bulletin Dedicated to Dr Ingham—The *Bulletin* of the Los Angeles Neurological Society for December was dedicated to Dr Samuel D Ingham, a former president of the society and clinical professor of medicine (neurology) at the University of Southern California School of Medicine, Los Angeles, as a tribute of esteem of members of the society and in recognition of his contributions to the specialty of neurology. Dr Ingham was born in Mehoopany, Pa., in 1876.

He graduated at the Medico-Chirurgical College of Philadelphia in 1899 and served on the staff there from 1907 to 1910 as instructor in neurology. He was clinical professor of nervous and mental diseases at Temple University School of Medicine, Philadelphia, from 1910 to 1920. He joined the staff of the Los Angeles County Hospital in 1921 and the faculty of the University of Southern California School of Medicine in 1931. He was chairman of the section on neurology of the California Medical Association in 1922, vice president of the American Neurological Association, 1936-1937, and chairman of the Section on Nervous and Mental Diseases of the American Medical Association, 1937-1938. He is now editor-in-chief of the *Bulletin* of the Los Angeles Neurological Society.

CONNECTICUT

Hospital News—A temporary 50 bed wing will be erected at the Bristol Hospital, Bristol, to cost about \$152,000. A grant of \$67,641 was made to the hospital by the Federal Works Agency in November, according to *Modern Hospital*. The project will provide a temporary wartime addition. It will be of stone, brick, mill and frame construction. Only the walls and foundations will be permanent enough to be retained after the war.

DISTRICT OF COLUMBIA

Personal—Rear Admiral Ross T McIntire, Surgeon General of the United States Navy and personal physician to President Roosevelt, received the honorary degree of doctor of science at the commencement exercises at Marquette University School of Medicine, Milwaukee, February 13.

Society Adopts Civilian Medical Care Program—A six point program to provide "adequate medical care for the civilian population in wartime Washington" was to be started immediately with a canvass of all physicians in the Washington Star announced on January 19. A committee on medical service for the District of Columbia was set up comprising representatives of the Medical Society of the District of Columbia, the U S Public Health Service, the Health Security Administration, the Emergency Medical Service for Civilian Defense and the Medico-Chirurgical Society. The plan was presented at a meeting of the district medical society on January 18 following its adoption by the newly organized committee. Its objectives are a canvass of all physicians to learn the patient load, establishment of panels of physicians for sections of the city to serve in emergencies and epidemics, and an inquiry into the system of rationing gasoline and tires (doctors say the system takes too much time from attention to the sick), educational program and preventive medicine to meet dangers of overcrowding and postwar planning. The new committee acted under the chairmanship of Dr A Magruder McDonald, president of the district society and district coroner. Practical phases will be worked out geographically on the basis of the selective service map of the district, with key physicians to be assigned with responsibility for certain areas. The executive board of the district society had at this time approved the project, but it was to be submitted to the entire society for final approval at a later meeting. Meanwhile according to the *Star* the program was to be put into immediate action by a canvass of all physicians "to determine the patient load each medical practitioner is carrying and the demands being made on him for medical service which he is unable to meet." Specialists will be asked to do general practice in the emergency. A committee of the society had in December announced a survey of wartime medical needs of Washington (*THE JOURNAL*, January 9, p 139).

IDAHO

Physicians in the Legislature—Physicians in the present session of the Idaho legislature are Drs Charles A Robins, St. Maries, and John D Shinnick, Grangeville. Dr Robins is serving his third successive term as state senator. He was elected president pro tem.

Appointments to State Examining Board—Gov. C A Bottolfsen, Boise, recently appointed the following members of the Idaho State Board of Medical Examiners: Drs Albert B Pappenhagen, Orofino; Frank C Gibson, Pottlatch; Casper W Pond, Pocatello; George C Halley, Twin Falls; Thomas A Ellison, St. Anthony, and Samuel M Ponder, Boise.

IOWA

New Director of Local Health Services—Dr Chester L Putnam, medical director of district health service number 8 with headquarters in Manchester, was recently appointed director of local health services for the state department of health. Dr Donald M Harris, Le Mars, medical director of district health service number 3, with headquarters in Spencer, was named to succeed Dr Putnam in the eighth district.

LOUISIANA

Personal—Dr Herbert Randolph Unsworth was recently installed as president of the New Orleans Neuropsychiatric Club and Dr Guy L Odom was chosen secretary-treasurer—Paul S Lavik, Ph D, has been appointed full time instructor in the department of biochemistry at Louisiana State University School of Medicine, New Orleans

Dr Matas Awarded Fraternity Medal—Dr Rudolph Matas, New Orleans, was recently presented with the medal of the Nu Sigma Nu degree of merit, the highest honor conferred by the fraternity. The award recognizes thirty years of service by Dr Matas to the group as a faculty member of Beta Iota Chapter of Tulane University of Louisiana School of Medicine, New Orleans, and as president of the National Honorary Council in 1935. The only other recipients of this medal have been Drs Frederick G Novy, Ann Arbor, Torald H Sollmann, Cleveland, James B Herrick, Chicago, and the late Drs Victor Vaughan, Detroit, Nicholas Senn, Chicago, John B McMurrich, Ste Anne de Bellevue, Quebec, William H Welch, Baltimore, Gottlieb C Huber, Ann Arbor, William H Park, New York, and John M T Finney, Baltimore

MASSACHUSETTS

Lecture on Tropical Medicine—Col Richard P Strong, M C Army of the United States, director of Tropical Medicine, Army Medical School Washington D C, delivered two lectures at the Harvard Medical School, Boston, January 26, on "Importance of Tropical Infectious Disease in the Present War" and "Diagnosis and Prevention of Plague and Cholera"

Dr Thorn Addresses Harvey Society—Dr George W Thorn, Hersey professor of the theory and practice of physic, Harvard Medical School, Boston, lectured at the Beth Israel Hospital, January 22, under the auspices of the William Harvey Society and Tufts College Medical School, Boston. His subject was "The Clinical Aspects of Sodium and Chloride Metabolism"

New Hospital House Journal—The *News*, official house publication of the Massachusetts General Hospital, Boston, recently made its appearance. It is intended not merely as a medium of communication to the staff and personnel but to distribute information about hospital activities and to give news of individual members. The hospital distributes the *News* to all alumni now on military duty as well as to members on the active staff.

Dr Blake Gives First Begg Society Lecture—Dr Francis G Blake, dean and Sterling professor of medicine, Yale University School of Medicine, New Haven, presented the first annual Begg Society Lecture at Boston University School of Medicine, January 28, on "Epidemic Diseases in Wartime". The Begg Society was founded about a year ago by a group of third and fourth year students at Boston University School of Medicine to promote good scholarship and fellowship. The recent lecture is the first in a lectureship which the society plans to sponsor annually. The Begg Society was established in honor of the late Dr Alexander S Begg, who at the time of his death was dean of the school of medicine.

MINNESOTA

Interstate Shipment of Abortifacient Paste Enjoined—On January 19 Hon Robert C Bell, U S District Judge for the District of Minnesota, signed an order granting a permanent injunction restraining the shipment in interstate commerce of a drug labeled 'Intrauterine Paste' or 'Dependon Products Paste' manufactured and sold by Anne M Jenks and Jenks Physicians' Supplies, White Bear Lake. The injunction followed a trial that commenced January 5 in St Paul. At the trial the government called forty-six witnesses, thirty-nine of whom were physicians. Of this number six were confessed criminal abortionists and a dozen or more were physicians who had used the paste in so called therapeutic abortions. The state board of medical examiners reports that the court, in its findings of fact, found that the paste as shipped in interstate commerce was composed mainly of potassium soap or other soft soap base with small quantities of alcohol, iodine and distilled water added. The court also found that the paste was represented to the medical profession and others as being safe and appropriate for introduction into the pregnant uterus, for the purpose of inducing labor, terminating pregnancy, and removing the retained portions of the products of conception. The court also found that the paste was represented as 'an effective medicament for the treatment of cervicitis, endometritis, dysmenorrhea, and cervical and uterine

discharges". As a result of the evidence, the court found that the paste "is unsafe and dangerous to health and has caused fatalities and serious injury. Among the specific dangers which are involved in and have resulted from its use are the extensive destruction of tissue, hemolysis or the destruction of the cellular portions of the blood, systemic potassium poisoning, extensive hemorrhage and prolonged bleeding, sterility, peritonitis, pulmonary embolism, damage to kidneys, liver and other internal organs, and increased susceptibility to infection". The court then found as a matter of law that the paste was misbranded and that its labeling was false and misleading and that "in truth and in fact it is ineffective for such purposes".

NEW JERSEY

Infectious Diarrhea of Newborn Made Reportable—At a meeting of the state department of health January 12, infectious diarrhea of the newborn was added to the list of reportable diseases.

Endowment Fund for Scientific Work—Plans are under way to establish an endowment fund in the Medical Society of New Jersey 'to support and encourage scientific work, as means and opportunity may be available'. This activity would be carried out under the newly organized committee on scientific work of the state society which is now functioning under the chairmanship of Dr William W Maver of Jersey City.

Gonococcus Culture Facilities Offered to Physicians—A new gonococcus culture service by mail was recently inaugurated by the state department of health. Culture stations have been established throughout the state where the physician to submit a specimen to be cultured for gonococci, must first obtain a culture outfit. After the specimen is obtained from the patient the outfit must be returned to the station within three hours. At the culture station the specimen will be incubated for eighteen to twenty-four hours and mailed to the laboratory of the state department of health. According to the state medical journal, it is recommended that whenever a culture is taken a smear be taken also. It is expected that the new service will materially aid in the reduction of gonorrhea in the state. The state journal points out that chronic gonorrhea in women is often relatively asymptomatic and very frequently smears are consistently negative. Cultures will detect a much higher percentage of the cases. Cultures have an additional advantage over smears in that they differentiate the gonococcus from other gram negative diplococci which may be merely contaminants.

NEW YORK

Graduate Lectures—Dr Frederick N Marty, Syracuse, will discuss "Plasma Therapy" before the Cortland County Medical Society at the Cortland County Hospital, Cortland, March 19, under the auspices of the state department of health and the state medical society. Dr Paul Reznikoff, New York, lectured under the same auspices on March 2 at the joint meeting of the Onondaga County Medical Society and the Syracuse Academy of Medicine on 'The Diagnosis and Treatment of Anemia'.

New York City

Personal—Dr Duncan W Clark, instructor in the department of medicine and director of the student health service, Long Island College of Medicine, Brooklyn, has been appointed assistant dean effective February 1. Dr Clark, who graduated at Long Island College in 1936, later was a Commonwealth Fund Fellow at Yale University School of Medicine, New Haven.—Raymond L Zwemer, Ph D, of the Columbia University College of Physicians and Surgeons has been elected an honorary member of the Sociedad de Medicina de Montevideo, Uruguay and a corresponding member of the Sociedad Argentina de biologia of the Asociacion Medica Argentina.

Dr Calderone Named Deputy Commissioner of Health—Dr Frank A Calderone, secretary of the city department of health since July 16, 1942, has been appointed deputy health commissioner to succeed George T Palmer, Dr PH who resigned on February 13. Dr Calderone graduated at the New York University College of Medicine in 1924 and served there as instructor in pharmacology and physiology from 1932 to 1936. After receiving his master's degree in public health at Johns Hopkins University School of Hygiene and Public Health, Baltimore, in 1937 he joined the New York State Health Department as epidemiologist. Later he was district health officer at the lower east side health center and currently is lecturer in the department of preventive medicine at the New York University.

SOUTH CAROLINA

Personal—Dr Charles C Ballard Allendale, has been appointed director of the Pickens-Oconee Health Unit—Dr Lee W Milford Clemson, school physician of Clemson College, was recently elected president of the Southern Conference, he was formerly vice president of the athletic group—Dr and Mrs Joseph H Saxe observed their fiftieth wedding anniversary in Sharon, January 11

Business Manager Appointed for State Association—Mrs Claude G Watson, Florence, who for two years has been working in the secretary's office has been elected business manager of the South Carolina Medical Association. This action was taken at a recent meeting of the council to increase the business efficiency of the association. Mrs Watson will continue to work in the office and under the direction of the secretary-treasurer and editor, Dr Julian P Price, Florence

VIRGINIA

Personal—Dr Robert Manton Wilson head of the medical and division of the Richmond Health Department, has been appointed coroner to succeed Dr John Hamilton Scherer who has resigned to devote his full time to private practice—Dr Powell G Dillard has been named city school physician of Lynchburg succeeding the late Dr John Paullett Clark

Nutrition in Wartime—The Medical College of Virginia announces a nutrition symposium to be held March 25-27 at the college, Richmond. Gov Colgate W Darden Jr will open the program with an introduction of Dr Irl C Riggan state commissioner of health who will discuss "Nutrition Plans of the State Department of Health." Other speakers on the program will be

Dr William H Sebrell Jr, Bethesda Md, "Nutrition in a Changing World."

India J Roberts, Ph D, Chicago, "Making Nutrition Vital."

Eleanor B Dietrick, M S, Blacksburg, "Victory Gardens as Related to Wartime Nutrition in Virginia."

Dr Virgil P Sydenstricker, Augusta Ga, "Rationing as It Affects Nutrition of the Public."

Washington OPA Representative (name not announced), "Living Under Rationing."

A dinner meeting will be addressed Friday evening by Dr Sydenstricker on "Wartime Nutrition in England." The sessions will conclude Saturday morning with a panel discussion on "Teaching Nutrition Material to Elementary School Children."

WEST VIRGINIA

Dr Crosson to Become Industrial Consultant for Sharp and Dohme—Dr John W Crosson, Charleston, since 1940 director of the bureau of industrial hygiene of the state department of health, has resigned to become industrial consultant for Sharp & Dohme. He will be attached to the medical research staff at Philadelphia.

Horatio Buonanno Permanently Rejected for License—Judge Julian I Bouchelle entered a final order, February 4, in the circuit court of Kanawha County forever prohibiting the Public Health Council of West Virginia from further considering the application of Horatio Buonanno Fairmont to practice medicine and surgery in West Virginia, according to an announcement from the state medical association. The action ends the case between the state medical association versus the West Virginia Public Health Council and Horatio Buonanno, although the final order provided that nothing therein should be construed as prohibiting Buonanno from obtaining a license by means of another examination regularly held under the provisions of the code. Buonanno was licensed to practice medicine in West Virginia on August 22, 1927. Prior to his admission to this examination he presented a diploma to the council which purported to show that he had successfully completed a course of study as prescribed by law being one of the prerequisites for examination and for the issuance of a license to practice. In 1928 the council ascertained that the diploma submitted by Buonanno was from a fraudulent school. In 1930 the license to Buonanno was revoked on the ground that he was guilty of dishonorable conduct having secured the license by fraud. Buonanno again appeared before the council in 1934 and presented a diploma purportedly issued by the University of Rio de Janeiro. The council learned that this diploma was not genuine and refused to reinstate the license. Since that time Buonanno has tried repeatedly to have his license reinstated. At a meeting of the council in November 1941 he was advised that the council would act on his application at the meeting to be held in March 1942. The West Virginia State Medical Association instituted a proceeding in March 1942 for the purpose of restraining the Public Health Council from further considering Buonanno's application. In a decision handed down by the

Supreme Court on Dec 8, 1942 the ruling of the circuit court of Kanawha County restraining the Public Health Council from further consideration of Buonanno's application for a license to practice medicine and surgery in West Virginia was affirmed.

WISCONSIN

Lippitt Memorial Lecture—Dr Marcy L Sussman, director of the department of radiology, Mount Sinai Hospital, New York, delivered the eighth annual Lippitt Memorial Lecture under the auspices of the Mount Sinai Hospital, Milwaukee, January 22. His subject was "Newer Concepts in the Diagnosis of Congenital Heart Disease."

Orthopedic Field Clinics—On January 1 the bureau for handicapped children of the state board of health started a series of orthopedic field clinics throughout the state for persons under 21 years of age. They will be continued until July 1, 1943. During 1941 and 1942, 1,033 children were examined at these field clinics. All referrals to the clinics for examinations must be made by the family physician. Parents and physicians are invited to attend the clinic with the child. If necessary, other services may be obtained in addition to orthopedic treatment.

GENERAL

Urologic Prize Will Not Be Awarded This Year—The American Urological Association announces that its annual research prize of \$500 will not be awarded this year and that plans for its June meeting in St. Louis have been canceled.

Meetings Postponed—The American Association for the Study of Gouters has announced that all meetings of the association will be postponed for the duration of the war. All the present officers will hold their positions until the next meeting of the association. The 1943 session of the American College of Chest Physicians has been canceled.

Special Society Election—Dr Robert Chobot, New York, was recently chosen president of the Society for the Study of Asthma and Allied Conditions, Dr Harry B Wilmer, Philadelphia (now deceased), was elected vice president, and Dr William Cook Span, New York, was reelected secretary. The 1943 meeting is tentatively planned for December in New York.

Dr McGinnes Appointed Director of Red Cross Midwestern Area—Dr G Ford McGinnes, director of venereal disease control division in the Tennessee Department of Public Health, Nashville, and associate professor of preventive medicine at the University of Tennessee College of Medicine, Memphis, has been appointed director of medical and health service of the midwestern area of the American Red Cross with headquarters in St. Louis. He succeeds Dr Howard B Mettel who died in November 1942. Dr McGinnes was formerly director of the bureau of communicable disease of the Virginia State Department of Health.

New Journal on Biochemistry—The *Archives of Biochemistry* recently made its appearance. Published by the Academic Press, New York, the new journal intends to cover the field of chemical structure and reactions of living organisms including proteins, hormones, vitamins, viruses, enzymology, biochemistry and biophysical research in chromosomes, metabolism, nutrition, photosynthesis, plant chemistry, organic chemistry as related to living organisms, colloid science in its biologic applications and chemotherapy. Manuscripts may be submitted to the editorial office of the *Archives*, 125 East Twenty-Third Street, New York, or to one of the editors:

Moses L Crossley, Ph D, American Cyanamid Company, Bound Brook, N J.

Fred C Koch, Ph D, Armour and Company, Research Department, Chicago.

Chne M McCay, Ph D, Cornell University, Ithaca, N Y.

Frederick F Nord, D Sc, Fordham University, New York.

Frits W Went, Ph D, California Institute of Technology, Pasadena, Calif.

Chester H Werkman, Ph D, Iowa State College, Ames, Iowa.

Foundation for the Study of Cycles Offers Prize—The Foundation for the Study of Cycles, New York, a nonprofit organization created to foster, promote and conduct scientific research in respect to rhythmic and periodic fluctuations in any branch of science, announces the offering of a medal to the person who, during 1943, published the book or paper that in the opinion of the judges is the most outstanding. The foundation is an outgrowth of the permanent committee set up at Matamek in Canada after the first International Conference of Biological Cycles. In its present form the foundation dates from 1940 at which time it was incorporated as a nonprofit organization under the laws of Connecticut. In addition to awarding a medal the foundation makes awards for outstanding work in each branch of science. The person who receives

the medal and the persons who receive the awards will also be elected fellows of the foundation. Additional information may be obtained from Ellsworth Huntington, Ph.D., chairman of the committee on awards, Hendrie Hall, Yale University, New Haven, Conn.

New Committee on Food Composition—The food and nutrition board of the National Research Council has organized a committee on food composition, under the chairmanship of Conrad A. Elvehjem, Ph.D., Madison, Wis., to collect, coordinate and appraise food composition data. The committee is to act as repository and point of dissemination for authentic data on all foods being used or considered for use by all branches of the military services. Proximate and mineral composition as well as analyses for vitamins A and C, thiamine, riboflavin and niacin are required as a basis for nutritional evaluation of these foods. Data on new products, processed foods and dehydrated meats, fruits and vegetables especially are needed. The committee has already enlisted the cooperation of federal and state laboratories throughout the country. However, it is also aware that a great wealth of food composition data have been accumulated in the course of research and routine analyses by industrial laboratories. It is the purpose of this communication to appeal to these laboratories of the food industries to make their data active in the war effort. The committee assures that data received for this purpose will be handled with such reservations as should be exercised in the official utilization of this information by the armed services only. Please address Paul L. Packer, Ph.D., secretary, Committee on Food Composition, National Research Council, 2101 Constitution Avenue, Washington, D.C.

Special Program Marks End of Science Talent Search—The second Science Talent Search to find potential science talent in high school graduating seniors throughout the nation ended with a special program in Washington, February 26-March 2 at which time the forty finalists including twenty-nine boys and eleven girls, met at the Science Talent Institute to compete in final examinations for Westinghouse science scholarships. The theme of the second annual search was 'Science's Next Great Step Ahead' and the recent program was designed to emphasize some things that will constitute the next great step ahead of science. One session was a panel discussion on vocational opportunities by authorities in special fields. The program included a nutrition luncheon and special broadcast over the Columbia Broadcasting System with an interview of Milburn L. Wilson, D.Sc., assistant director in charge of nutrition, Office of Defense Health and Welfare Services, by Watson Davis, director of Science Service, on "Nutrition in Wartime." At other sessions the speakers included Hugh S. Taylor, Sc.D., Princeton, N.J., on "Molecules and the Future of Chemistry," Eleanor A. Bliss, Sc.D., Baltimore, "Advances in the Sulfonamide Drugs," Dr. Warren H. Lewis, Philadelphia, "Cancer Cells," and Edwin G. Conklin, Sc.D., Princeton, N.J., "The Biological Future." At the banquet Dr. Thomas Parran, surgeon general of the United States Public Health Service, was among the speakers.

Research in Mental Hospitals—The National Committee for Mental Hygiene, New York, has recently published a report on "Research in Mental Hospitals—Study Number Two" describing investigations of causes and treatment under way by five hundred investigators in seventy-nine research centers under private auspices, such as general and mental hospitals, clinics, medical schools and universities, located in thirty-nine cities and towns in twenty-two states and the District of Columbia. The first study, issued by the committee in 1938, was a survey of research in state hospitals and other tax-supported institutions for the mentally ill and defective. Both surveys were made in cooperation with and through funds provided by the John and Mary R. Markle Foundation. According to an announcement these surveys are designed to clear the way for further progress in dealing with a major medicosocial problem that takes an enormous toll both of individual lives and of individual and community wealth and that shows signs of becoming even more serious. The magnitude of the problem is reflected in a 'great and ever growing demand for hospital and clinic accommodations for the care and treatment of sufferers from mental and nervous disorders.' Many phases of neurotic and psychotic disorders are covered at certain research centers. Insulin and other shock therapies in treating mental disorders are studied at other centers. Some groups emphasize research on organic symptoms resulting from emotional stress and from the so-called psychosomatic disorders; others deal with industrial psychiatry, child guidance studies of marital relations, case work with retarded and delin-

quent children, alcohol and drug addiction, sex variants, suicide symptoms, epilepsy, hypnosis, fever treatment in dementia, paralytica, prolonged sleep therapy in psychoses and various behavior deviations as well as all types of mental disorders and treatments.

CANADA

National Program on Nutrition—A national nutrition program was inaugurated in January, according to the *Canadian Journal of Public Health*. Educational movements were directed by the division of nutrition services of the Dominion Department of Pensions and National Health, the Wartime Information Board and the Association of Canadian Advertisers. The entire program has been designed to educate Canadians to the need of adequate nutrition for the maintenance of health and physical efficiency and arose from dietary surveys carried out throughout the Dominion.

FOREIGN

Forty Million Dollar Health Foundation—William Richard Morris, British motor magnate and philanthropist who bears the title of Lord Nuffield, has given \$40,000,000 to form a "Nuffield Foundation." According to the Associated Press, February 13, income from this capital will be used to assist medical research and teaching, organization and development of medical and health services, scientific research, and teaching in the interests of trade and industry, pursuit of social studies, and the care and comfort of aged persons.

Deaths in Other Countries

Sir Robert Armstrong-Jones, formerly president of the Royal Medico-Psychological Association, president of the psychiatry section of the Royal Society of Medicine in 1929 and former secretary of the psychology section, Congress of Hygiene and Demography in London, died in London, January 30, aged 86. Sir Robert was first superintendent of the London County Council Asylum, Woodford, a position he held for twenty-three years. One of the Lord Chancellor's Visitors in Lunacy from 1921 to 1931, Sir Robert had been a member of the Advanced Board of Medical Studies, University of London.

CORRECTION

Annual Report of Hospital Service—In the Philadelphia item entitled "Annual Report of Hospital Service" (THE JOURNAL, February 20, p. 610) Dr. Lucius R. Wilson should have been reported as medical superintendent of the Hospital of the Protestant Episcopal Church instead of medical superintendent of the Protestant Episcopal Church.

Government Services

Office of Indian Affairs Now in Chicago

The United States Department of the Interior announces that the Office of Indian Affairs is now located in the Merchandise Mart Building, Chicago, where it was moved from Washington. Dr. John R. McGibony, director of health, states that all communications concerning employment and health questions should be addressed to the Chicago office.

Treatment Centers for Venereal Disease

Treatment centers will be set up with Lanham Act funds in eight states, the Canal Zone and the Virgin Islands. Equipped for treating women infected with venereal disease, the centers will provide medical care designed to cure early syphilis and gonorrhea. Treatment in most cases will take about a week, with four or five weeks for observation and medical supervision. In addition to medical treatment the centers will provide some form of vocational guidance. Attempts will be made to find profitable employment for the patients on their release and, when feasible a certain amount of vocational training may be provided during the observation period. A center with accommodations for 200 beds is planned for the Canal Zone. Six hundred beds are planned for the three centers in Florida at Wakulla, Sarasota and Ocala; in Algiers, La. 200; Mississippi, 50; Monett, Mo. 25; Rush Springs, Okla. 50; Goldville and Pontiac, S.C. a combined 400; Knox County, Tenn. 200; and St. Thomas, V.I. 25.

Warning as to the Dose of Morphine for the Wounded

In a bulletin on the use of morphine in shock, the War Office points out that the dosage after injuries cannot be standardized, but current variations are perhaps unnecessarily wide. At times of stress the medical officer may be tempted to give considerably more than the ordinary initial dose of a quarter of a grain (0.016 Gm.) but he should remember that the ideal is to use the least dose which will be effective and that anything over half a grain (0.032 Gm.) is likely to increase the symptoms of shock and may depress the respiratory center. For severe injuries with much pain and distress an initial dose of half a grain of morphine hydrochloride or tartrate is reasonable. But, if the full dose is given, no more should be administered for at least four hours.

Disappointing results from the smaller doses are often due to poor absorption, for, in the seriously shocked, morphine may act slowly or irregularly when given subcutaneously. Intramuscular injection is preferable, and when relief of pain is urgent more use should be made of the intravenous route. An intravenous dose of $\frac{1}{8}$ grain (0.01 Gm.) or $\frac{1}{4}$ grain (but never more), diluted to at least 1 cc. with sterile water and injected over a period of a minute or more, will reduce pain almost immediately. When injection is impossible, two $\frac{1}{4}$ grain tablets may be placed beneath the tongue.

It is also pointed out that morphine is given to many patients who would be better without it. It should be used when pain needs relief but should not be given as routine to all who seem the worse for injuries. For some of these a cup of tea would be more appropriate.

Compulsory Treatment of Venereal Disease Opposition Defeated

As usual in war there is an increase of venereal disease, which is engaging the attention of the government. Free treatment under conditions of complete secrecy has been available in Britain for twenty-five years. There are now two hundred and forty-nine treatment centers, three fourths of which are in hospitals. Eighteen new centers have been provided since the war began and five more are about to be opened. The demand for specialists and other medical staff for the fighting forces has made the staffing of the new centers difficult. There was no compulsion before the government recently made a regulation that any person who was shown to have communicated a venereal disease to two persons must attend for treatment. But this regulation has been opposed by certain politicians, mainly women. In the House of Commons Dr. Edith Summerskill (physician) moved a resolution for its annulment. She declared that it would be ineffective and would delay real action. During the last year 70,000 new cases of venereal disease came to the civilian clinics. If to these were added those which did not come, the number might be 150,000. To these must be added the number of cases in the fighting forces. The regulation would not protect the men of the country against venereal disease. No two men would inform on a respectable woman who had been infected innocently. The regulation would get only a few women, probably a few prostitutes and a few other unfortunates. She advocated the compulsory notification and treatment of all cases, as in Sweden, where the default rate was only 2.5 per cent in 1935.

In the debate Sir Francis Freeman (expert in public health) said that the question was: What was going to be effective at present? The regulation was a useful step and all that could

be done now. What was the good of pretending to set up clinics when we had not the doctors to man them and could not get them while the war continued? Dr. Haden Guest (physician) supported the regulation. In the fighting services, where there were both compulsory notification and compulsory treatment, there was a tremendous rise in venereal infection. Sir Ernest Graham Little (dermatologist) said that we should regard the curve of incidence of venereal disease as an epidemic. Something must be done here and now. We must get at the centers of infection here and now. The compulsory treatment of the regulation was valuable, because, although not cured of syphilis by one or two injections, a person was rapidly rendered non-infective. The resolution against compulsory treatment was rejected by a majority of 245 votes to 31.

The Phonoelectrocardioscope

A new instrument, which its inventor, G. E. Donovan, calls the phonoelectrocardioscope, was described by him in a lecture to the Institution of Electric Engineers. Though it has not yet passed out of the engineering stage, it promises to be useful to the clinician and research worker. The instrument incorporates a double beam cathode ray oscilloscope with a fluorescent screen of long afterglow, which permits the simultaneous direct visual recording of two phenomena such as the phonocardiogram and the electrocardiogram, the phonocardiogram and the sphygmogram or the electrocardiogram and the sphygmogram. At the same time the heart sounds, picked up by a special microphone, can be heard through an electrical amplifying stethoscope or a loud speaker. It is claimed that the instrument is reasonably simple to work, it cannot be damaged by overloading or shock and maintenance is simple. A further advantage is that permanent photographic records can be taken of the phonocardiogram, electrocardiogram or sphygmogram. By means of frequency filters, murmurs or other desired sounds can be accentuated and undesirable ones excluded. The instrument has an overall frequency range extending from the lowest frequency to over 1,000 cycles per second, but this band can be divided by means of filters so that the frequency response can be given any desired slope as is done in the tone control of a wireless set.

The most obvious application of the phonoelectrocardioscope is in the teaching of auscultation. Donovan states that the amplification of heart sounds through a loud speaker can never be 100 per cent satisfactory. He prefers multiple head phones, which can be used with his instrument. By means of it a group of students can hear and "see" the sounds produced by the heart, including those not audible in the ordinary stethoscope.

The Jubilee of the Clinical Journal

The centenary of the *British Medical Journal* was celebrated two years ago (*THE JOURNAL*, Dec. 14, 1940, p. 2099). The *Clinical Journal* has now celebrated its jubilee by a special issue which takes the place of an ordinary one and is no larger, thus keeping to the paper restrictions imposed by the war. It began publication in 1892 to provide clinical teaching by means of lectures, articles and records of cases. A series of articles by leading clinicians includes "Some Medical Aphorisms" by Sir Arthur Hurst, "Trial and Error in Endocrinology" by Sir Walter Langdon-Brown, "Irregularities of Cardiac Rhythm" by E. M. Brockbank, "Some Remarks on Perforated Peptic Ulcer" by V. Zachary Cope, "The Progress and Present Aspects of Medical Science" by Prof. J. A. Ryle, "What Do We Mean by Normal?" by Prof. D. M. Lyon, "Bleeding After the Menopause" by A. C. Palmer, "The Importance of Early Diagnosis of Cancer of the Cervix" by W. F. T. Haultain and "Practical Reflections on Some Genitourinary Conditions" by A. E. Roche. Among the congratulations, Professor Ryle refers to "this honest and helpful periodical, which goes its way unruffled by swift change or novel methods or the impatience of a specialist age."

JERUSALEM, PALESTINE

(From Our Regular Correspondent)

Jan 3, 1943

The Fight Against Epidemic Diseases

As a consequence of the disturbances in this country in 1936-1938 and after that of the war, a considerable increase in epidemic diseases has been recorded in Palestine. Reports published by various medical institutions convey a clear picture of the present situation. Thus in December 1942 Dr. Katzenelson gave an account of the activities of the health department of the Waad Leumi.

With regard to the present typhoid epidemic he points out that, in contradistinction to England with its population of 40 millions, less than 2,000 cases of typhoid were reported in Palestine, however, with a population of slightly more than 1½ million, had a case incidence of 2,500. In rather a small district (the Ein Geb settlement) on the trans-Jordan side of the Lake of Galilee at present 50 out of a total population of 300 are suffering from typhoid.

Braun and Dreyfuss, at the meeting of the Jewish Medical Association of Palestine, spoke about typhoid in Jerusalem in 1940-1941. Reviewing the situation from a clinical standpoint (in the "Refuah," the *Journal of the Palestine Medical Association*, May 15, 1942), they wrote as follows: A greater frequency of enteric fever was observed in Jerusalem during the second half of 1940 and during 1941. Not only in its numbers but also in its severity did typhoid and paratyphoid fever assume the character of a new epidemic. While in former years (1935-1939) no case of death occurred among 114 cases in the medical department of the Hadassah Hospital, 11 cases of enteric fever out of a total of 135 cases were fatal during the period. The clinical course was characterized by its length, its tendency to recurrences and its toxic manifestations. Toxicemia manifested itself by frequent occurrence of rigors, collapses and delirious states. The usual complications of these diseases were more frequent, besides, some rather unusual complications were observed. In a relatively large number of cases ulcerations of the throat were to be seen, in 1 case leading to extensive gangrene of the mouth and throat and so causing a lethal outcome. Other complications were hepatic jaundice, lobar pneumonia and muscular abscess. Avitaminotic states occurred quite frequently, especially of the vitamin B complex and vitamin C.

Another infectious disease which plays an important part in this country is tuberculosis. In the article referred to Katzenelson also criticizes the lack of support given by the government to the maintenance of the antituberculosis campaign. "In fighting the disease the only aid given by the government was a grant of £2,200 toward the maintenance of the Safad Hospital, whose annual budget was £10,000. Other tuberculosis hospitals received no support whatever, nor did the antituberculosis league have any help."

Nine cases of smallpox have been reported in Palestine during the last months, six of which occurred in Haifa, 2 in Beersheba and 1 in Tel Aviv. It was found that the infection had been introduced from Syria (Damas). In case of an emergency large quantities of vaccine can now immediately be made available.

Another 10 cases of plague, preponderantly in the Jaffa-Tel Aviv district, followed those reported from Haifa early in this year. Five of the patients died. Energetic measures to fight the disease were immediately taken by the government, including the establishment of a separate plague department in the Bnei-Brak Hospital near Tel Aviv, to which a special plague laboratory has been attached.

Katzellenbogen reports on vaccination against Jericho boil. Jericho boil is common among the workers of the potash plant on the Dead Sea and with the continued introduction of new

labor from Leishmania-free places the problem of prophylaxis has become one of practical importance. For inoculation Leishmania tropica cultures were used which had been taken from a local case and, moreover, Leishman-Donovan bodies of the same strain from the spleens of infected Syrian hamsters.

Of 167 vaccinated persons, 152 could be kept under close observation for six to ten months. Only 7 of them developed the symptoms of leishmania, partly at the site of injection, partly elsewhere. It is assumed that in these cases vaccination coincided with the incubation period of a natural infection. The others remained healthy.

The chemotherapeutic use of halogenized phenols was studied by Bernhard Zondek at his department at the Rothschild Hadassah University Hospital in Jerusalem. In cooperation with the Teva works he was able to prepare a p-chloro-xylenol solution suited for intramuscular injection. It is a special advantage of this compound that it is bactericidal wherever it is allowed to display its activity, be it in the blood stream, where it circulates after administration, or in the urine, where it is eliminated, or even on the skin after external application. Since the active principle is absorbed by the skin, a 15 to 30 per cent ointment was prepared, 10 to 20 Gm of which is applied on the skin on five successive days. Satisfactory clinical results with this method were recorded in pyelitis, cystitis and puerperal infection.

Palestine Health Report

Dr. H. G. H. Smart, medical adviser to the colonial secretary, who left Palestine after a short visit in September 1942, summarized some of his impressions.

"During my tour I have been much impressed by the community service that is so abundantly provided especially by the Jewish community. I have managed to learn a good deal about this and have visited Jewish hospitals and centers near Tel-Aviv and Haifa.

"I have also had the opportunity of visiting the Hadassah Medical Center recently completed after a long period of planning and careful thought. It is first class in every respect.

"The Jewish community in Palestine have a wealth of well known and highly trained scientists and doctors and they are employing this invaluable asset to the greatest advantage in the country."

Marriages

THEODORE WILLARD WEEKS JR, Moore Haven, Fla., to Miss Anna Florence Joyner of Farmville, N. C., in Baltimore, December 30.

JAMES MAC SAMS, Erwin, Tenn., to Miss Mary Elizabeth Jones of Johnson City, Tenn., in Blackstone, Va., February 5.

THOMAS STRINGFIELD JR, Waynesville, N. C., to Miss Harriet Cutler Coburn of Asheville in Biltmore, February 3.

HENRY M. WILSON JR, Peoria, Ill., to Miss Eleanor Rain of Jerseyville, Ill., in St. Louis, January 30.

EMMETT THOMAS FITZPATRICK to Miss Rose Mary Albury, both of Miami Beach, Fla., January 23.

HARRY L. ALPERT, Syracuse, N. Y., to Miss Harriet R. Ferst in Fayetteville, N. C., in January.

FRANK A. MANZIONE to Miss Mary Gabriella Kinney, both of Paterson, N. J., December 27.

WILLIAM KENNEDY KERR, Greenville, S. C., to Miss Rosa Burch in Columbia, January 26.

LESLIE E. HILDEBRAND to Miss Kathleen Corrigan, both of Spokane, Wash., December 30.

PAUL ELSBERG, Washington, D. C., to Miss Elizabeth Swartz, in Alexandria, Va., recently.

CARL B. SPUTH JR to Miss Ruth Agnes Means, both of Indianapolis, February 10.

PAUL L. KISTNER, St. Louis, to Miss Nina Gleeson of Ferguson, Mo., February 20.

LOUIS HANMAN to Miss Marion Campbell Bond, both of Baltimore, February 6.

Deaths

Emerson Frank Root, Salt Lake City Western Reserve University Medical Department, Cleveland 1880 member and past president of the Utah State Medical Association past president of the Salt Lake County Medical Society and the Pacific Northwest Medical Society, formerly chief of staff of the Holy Cross Hospital fellow of the American College of Surgeons in 1930 was given a testimonial dinner by 150 members of the profession from all parts of the state to celebrate his completion of fifty years in the practice of medicine, aged 84, died, January 18 of carcinoma of the rectum and bladder

Frederick Casimir Simon St Louis Missouri Medical College St Louis, 1899 specialist certified by the American Board of Otolaryngology member of the American Academy of Ophthalmology and Otolaryngology fellow of the American College of Surgeons served during World War I and in the U S Public Health Service on the staffs of the U S Marine Hospital Kirkwood, the Evangelical Deaconess Home and Hospital and the Lutheran Hospital aged 64 died December 31 in the Veterans Administration Facility Jefferson Barracks of generalized arteriosclerosis and pneumonia

Peter Whitman Rowland Jr Memphis Tenn, University of Virginia Department of Medicine Charlottesville, 1919 specialist certified by the American Board of Internal Medicine formerly assistant professor of medicine at the University of Tennessee College of Medicine member of the American Heart Association and the American Diabetic Association fellow of the American College of Physicians for seventeen years associated with the Crisler Clinic on the staff of the Methodist Hospital, aged 49 was found dead, January 10 of acute coronary thrombosis

Arden Cline Hornbeek Marlin Texas University of Texas School of Medicine Galveston 1920 fellow of the American College of Surgeons past president of the Falls County Medical Society and the Twelfth District Medical Society, Federal jail physician of Falls County local surgeon for the Southern Pacific and Missouri Pacific Railroads, examining physician for the state highway department of Falls County, chief surgeon of the Buie Clinic and the Buie Animal Hospital, aged 45 died January 20, of carcinoma of the spine

William Martin Barnes Henderson Tenn Memphis Hospital Medical College 1909 aged 59 died January 10 in the Baptist Memorial Hospital Memphis, of pneumonia

George Thomas Barrett, Erie Pa, Georgetown University School of Medicine Washington D C 1908, member of the Medical Society of the State of Pennsylvania, on the staff of St Vincent's Hospital aged 57, died, January 1, of cerebral hemorrhage

Edwin Abraham Beard Inglewood Calif College of Physicians and Surgeons Keokuk, Iowa 1898 served on the staffs of the Eye and Ear Hospital, Los Angeles, and the Centinela Hospital, aged 72, died, January 4, of coronary thrombosis

Nahum Binderman, Brooklyn Fordham University School of Medicine, New York, 1912, served on the staff of the Manhattan General Hospital New York, aged 60 died January 22 in the Israel Zion Hospital of coronary sclerosis, coronary thrombosis and pulmonary infarction

Cluese A Blanchard, Augusta Ga, University of Georgia Medical Department, Augusta 1892 member of the Medical Association of Georgia, aged 72, died recently of coronary occlusion

Clarence Roy Blosser Dunkirk, Ohio Ohio State University College of Medicine, Columbus, 1912 served during World War I, aged 58, died, January 17, of cerebral hemorrhage

Charles Jesse Brockway, Brookston, Ind Jefferson Medical College of Philadelphia, 1911 member of the Indiana State Medical Association, served in the medical corps of the U S Army in France during World War I aged 54 on the associate staff of the Lafayette Home Hospital, where he died, January 8, of cerebral hemorrhage

William Franklin Byler, Webb City Mo, University of Louisville (Ky) Medical Department 1904 aged 68, died, January 1, in Lebanon of hemangioendotheliosarcoma of the spleen

James Castle, Lynn Mass St Louis College of Physicians and Surgeon 1893 aged 85 died January 8 of heart disease

Louis Ballantine Chapman New Rochelle, N Y, Cornell University Medical College, New York 1908, president of the medical board of the New Rochelle Hospital, where he was a member of the board of directors and associate director of medicine, at one time medical director of the Grasslands Hospital, Valhalla, aged 64, died, January 9, of coronary occlusion

Jesse Franklin Cogan Dawson Pa, Baltimore Medical College 1892, in June 1942 received a certificate for fifty years practice of medicine from the Medical Society of the State of Pennsylvania, at one time a druggist, aged 77, died, January 1 of cerebral arteriosclerosis

Francis James Coleman, Kuna, Idaho Sioux City (Iowa) College of Medicine, 1897 University of Buffalo School of Medicine 1899 aged 74, died, January 2, of arteriosclerosis

John Philip Cooney, Providence R I, College of Physicians and Surgeons, New York, 1892, member of the Rhode Island Medical Society for many years on the staff of St Joseph's Hospital, a member of the school committee of Providence, member of the medical staff of the St Vincent de Paul Infant Asylum, aged 72, died, January 15, of heart disease and hypertension

Charles P Cooper, Chicago, Bennett College of Eclectic Medicine and Surgery Chicago 1906 on the courtesy staff of the Provident Hospital aged 60, died, January 19, of cerebral hemorrhage and hemiplegia

Robert Cowger, Draville, Ark Memphis (Tenn) Hospital Medical College, 1902, aged 70, died, January 16 of heart block

Hamilton Chalmers Cruikshank, Toronto Ont, Canada, University of Toronto Faculty of Medicine 1919 served overseas with the Royal Canadian Army Medical Corps during World War I deputy medical officer of health for Toronto for many years medical officer of the Manufacturers Life Insurance Company, aged 54, died, December 25

Charles W Culp, Hoyt Kan, Beaumont Hospital Medical College St Louis, 1893, aged 74, died, January 12, of cirrhosis of the liver

Arland Lewis Darling, Corning N Y University of Buffalo School of Medicine 1892 member of the Medical Society of the State of New York, aged 72 died December 13 of cerebral hemorrhage

Nicholas Leeke Dashiell Baltimore University of Maryland School of Medicine, Baltimore 1882 aged 82 died January 8 in the Union Memorial Hospital of injuries received when struck by a trolley car

Charles E Doubleday Penn Yan, N Y Syracuse University College of Medicine 1887 past president of the Yates County Medical Society aged 78 on the staff of the Soldiers and Sailors Memorial Hospital where he died January 14 of cerebral hemorrhage

Frank P Dunn Webster Groves Mo, Marion Sims College of Medicine St Louis, 1898, aged 72 died, January 13 of senility

Louis Joseph Ferrara New York University and Bellevue Hospital Medical College, New York 1910 member of the Medical Society of the State of New York served on the staffs of the Fordham, Mother Cabrini Memorial and Westchester Square hospitals and University Heights Sanitarium, aged 55, died January 19, of pulmonary fibrosis

Merle d'Aubigne Flenner Hamilton Ohio, Miami Medical College, Cincinnati 1903 aged 64 member of the staff of the Mercy Hospital served as chief of the medical staff of the Fort Hamilton Hospital, where he died, January 3, of coronary thrombosis

Royal L Garner Milan, Mo, Beaumont Hospital Medical College St Louis, 1900 an Affiliate Fellow of the American Medical Association, aged 81, died, January 4 of arteriosclerosis and chronic myocarditis

Thomas Cary Geron, Paris Texas, Medical Department of Tulane University of Louisiana, New Orleans, 1901, served for many years as health officer of Lamar County, on the staff of St Joseph's Hospital, aged 75, died, January 2, of coronary thrombosis

Alonzo Glass, Creal Springs Ill Marion-Sims College of Medicine, St Louis, 1897, aged 83, died, January 17, of uremia and chronic nephritis

Clark S Glover, Russellville, Mo, American Medical College, St Louis 1901, member of the Missouri State Medical Association served as deputy state health commissioner for Cole County for many years aged 68 died, January 5, of chronic myocarditis

Joseph Franklin Grist, Magazine, Ark (licensed in Arkansas in 1903) aged 73, died December 5, of angina pectoris

Leon Quitman Hall, Jackson, Miss, Memphis (Tenn) Hospital Medical College, 1913, member of the Mississippi State Medical Association, aged 55, died, December 31, in the Mississippi Hospital of angina pectoris

Charles Benton Harpole, Evansville, Ind, Chicago Homeopathic Medical College, 1893 at one time on the staff of the Protestant Deaconess Hospital, aged 77, died, January 10, of gastric hemorrhage

William Gillespie Harris, Plano, Texas, Medical Department of Tulane University of Louisiana, New Orleans, 1892, member of the State Medical Association of Texas, on the staff of the McKinney (Texas) Hospital, aged 84, died, December 4, of cerebral hemorrhage

Richard Tahaferro Henry, Springfield, Ark, University of Arkansas School of Medicine, Little Rock, 1911, member of the Arkansas Medical Society aged 60, died, January 4, of coronary occlusion

Christopher Henry Herbert, Jackson, Miss, Medical Department of Tulane University of Louisiana, New Orleans 1905, served on the board of trustees of the old Mississippi State Hospital for the Insane from 1900 to 1904 also a druggist, served on one of the city's first board of aldermen, aged 76, died, January 13, of arteriosclerosis

Edward Herzog * Bogota, N J, Univerzita Komenského Fakulta Lekarska Bratislava, Czechoslovakia 1920, aged 49, died, December 27, in the Holy Name Hospital, Teaneck, of coronary occlusion

Kenneth Jastram Holtz * Seattle, Jefferson Medical College of Philadelphia 1912, member of the Radiological Society of North America Inc, served as secretary of the Washington State Radiological Society, served during World War I, x-ray specialist at the Polyclinic, aged 52, died, January 9, of angina pectoris

George Thomas Hopkins, Paragould, Ark, Vanderbilt University School of Medicine Nashville, Tenn, 1893, aged 73, died, January 7, of ruptured abdominal aneurysm

William Bouldin Hopkins * Jeffersonville, Ind University of Louisville (Ky) Medical Department, 1921, member of the Kentucky State Medical Association member of the staff of the Clark County Memorial Hospital aged 51 died, January 1, in the Louisville (Ky) General Hospital of coronary occlusion

Simon Andrew Huber, Charter Oak Iowa, John A Creighton Medical College, Omaha, 1908 aged 61, died, December 10, in Sioux City of cirrhosis of the liver

John Austin Hunter, West Middlesex, Pa, Western Pennsylvania Medical College, Pittsburgh 1894 member of the Medical Society of the State of Pennsylvania, on the courtesy staff of the Christian H Buhl Hospital Sharon, aged 72, died, January 3, of chronic myocarditis

J Frank Huss, Atlanta, Ga, Southern Medical College, Atlanta, 1894 aged 71, died, January 9 of hypertension and heart disease

Clifford C Johnson * Harpers Ferry, W Va, Physio-Medical College of Indiana, Indianapolis, 1905, aged 63, died, January 18, of coronary thrombosis

J Leon Jones, Los Angeles, University of Wooster Medical Department, Cleveland 1910, served in the U S Army during World War I, aged 58, died, January 4, of myocarditis and arteriosclerosis

George M Jordan Frost, W Va (licensed in West Virginia in 1896), aged 87 died, December 8, of senility

Samuel Kavinoky * Buffalo, University of Buffalo School of Medicine, 1905 also a pharmacist, aged 68, died, January 23, of coronary occlusion

Frank Emil Klauser, Toledo, Ohio, Detroit Medical College, 1879, aged 86, died, January 17, of myocardial degeneration

Robert Keneborough Black Knowles, Vegreville, Alta, Canada Harvard Medical School, Boston 1902, aged 65, died November 16

Horace W Kohler, Red Lion, Pa College of Physicians and Surgeons, Baltimore, 1911 aged 51, died January 4, of coronary thrombosis

Fred Herman Kruse * San Francisco University of California Medical School, San Francisco, 1915 clinical professor of medicine at his alma mater, specialist certified by the

American Board of Internal Medicine member of the American Gastro Enterological Association and the National Gastroenterological Association, fellow of the American College of Physicians aged 63, died, January 14 of carcinoma of the prostate with metastases

David Charlton La Grone, Midville, Ga, University of Georgia Medical Department, Augusta, 1908 mayor of Summertown for six years, for a number of years surgeon for the Georgia and Florida Railroad, aged 57, died, January 12, in a hospital at Columbia S C, of cerebral hemorrhage

Orville Nelson Lewis, Haverstraw, N Y, Long Island College Hospital, Brooklyn, 1903, member of the Medical Society of the State of New York, served on the staffs of the Nyack (N Y) Hospital and the Good Samaritan Hospital, Suffern, aged 63, died, January 9, of coronary occlusion

Brady Forest Long, Mifflin Pa Baltimore University School of Medicine, 1900, member of the Medical Society of the State of Pennsylvania, aged 69 died, November 6, in the Lewistown (Pa) Hospital of cardiorenal vascular disease

William Orville Manion, Portland Ore, College of Physicians and Surgeons, Keokuk, Iowa, 1886 served during World War I formerly on the staff of the Veterans Administration Facility aged 80 died, December 5 of chronic myocarditis

Albert James Marks, Toledo Ohio Physio Medical Institute Cincinnati 1882, Civil War veteran, aged 100 died, January 21 in the East Side Hospital of a fractured hip as the result of a fall, and senility

Louis Lynn Marshall, Little Rock Ark, Eclectic Medical University Kansas City Mo 1912 Kansas City (Mo) College of Medicine and Surgery 1916 formerly a member of the Eclectic State Medical Board aged 61, died January 16, of chronic lymphatic leukemia

Robert Lee Montgomery, Tusculum Ala Memphis (Tenn) Hospital Medical College 1903 member of the Medical Association of the State of Alabama aged 72, died December 28, of cerebral hemorrhage

Nicholas L Mulvey, Syracuse N Y Niagara University Medical Department, Buffalo, 1890, member of the staff of the Crouse-Irving Hospital on the staff of the Women's and Children's Hospital, now known as the Syracuse Memorial Hospital, from 1902 to 1913 aged 81 died, January 6, of cerebral hemorrhage and colitis

Arthur Irwin Murphy * Pittsburgh University of Pennsylvania Department of Medicine Philadelphia 1908, member of the American Urological Association aged 59, a member of the staff of the Western Pennsylvania Hospital, where he died, January 17, of pneumonia

Paul Nathaniel Neal * Raleigh N C Harvard Medical School, Boston, 1919 medical director of the Durham Life Insurance Company aged 48 died January 12 in the New England Baptist Hospital Boston of esophageal diverticulum following an operation for mediastinal abscess, emphysema and pericarditis

Benjamin Cecil Perry * Bethesda, Md Baltimore Medical College, 1906, member of the state board of health at one time president of the Montgomery County Board of Commissioners member and at one time chairman of the Maryland-National Capital Park and Planning Commission served as vice president of the Bank of Bethesda, aged 61 died January 8 in the Georgetown University Hospital, Washington, D C, of chronic cardiovascular degeneration

Alexander Fraser Pirie, Dundas, Ont Canada Queen's University Faculty of Medicine, Kingston, 1887 died, November 24

John Edmond Powell, Westmount, Que Canada, McGill University Faculty of Medicine, Montreal, 1940, commissioned a surgeon-lieutenant in the Royal Canadian Naval Volunteer Reserve, aged 25, was killed when his ship an airplane carrier was blown up while on convoy near Gibraltar, November 15

Rose M T Reading, Chicago, Bennett College of Eclectic Medicine and Surgery, Chicago, 1886, aged 75, died, December 22 in Elgin, Ill, of chronic myocarditis and bronchopneumonia

Edmonds Droke Rollins, Bristol Va University College of Medicine, Richmond, 1909, aged 55, died, January 6, at his home in Bristol, Tenn, of carcinoma of the throat

Fred Ernest Ross * Erie Pa, University of Buffalo School of Medicine 1897, medical director of Erie County, served on the staffs of the Hamot and St Vincent's hospitals aged 70 died, January 10 of heart disease

Joseph Francis Ruiz, San Jose, Calif., Creighton University School of Medicine Omaha, 1939 appointed an assistant surgeon, with rank of lieutenant, junior grade, U S Naval Reserve, March 11 1941 reported to a Marine division for active duty April 22, 1941 promoted to the temporary rank of lieutenant on June 15 1942, killed in action at Guadalcanal while on duty with a Marine division, November 11, aged 27

Pietro Sarli, Pittston, Pa., Regia Università di Napoli Facoltà di Medicina e Chirurgia Italy, 1908, aged 63, died, November 1, in the Mercy Hospital, Wilkes Barre, of empyema of the gallbladder and liver abscess

Gustav Sass, New York, Medizinische Fakultät der Universität Wien, Germany, 1929, member of the Medical Society of the State of New York, aged 38, died, December 27, of sarcoma

Joseph Scheidler, Chesaning Mich. University of Michigan Homeopathic Medical School, Ann Arbor, 1901, aged 70 died, December 3, in the University Hospital, Ann Arbor, of coronary occlusion and arteriosclerotic heart disease

William Charles Schmidt Sr. Cincinnati, Miami Medical College Cincinnati, 1900, aged 73, on the staffs of the Little Sisters of the Poor, Aged and Infirm, St Francis Hospital and the Good Samaritan Hospital where he died, December 18 following a prostatectomy

Leo Sebastian Schumacher, Lakewood, Ohio, St Louis University School of Medicine, 1910, on the staffs of St John's Evangelical Deaconess and St Alexis hospitals, Cleveland aged 55, died, December 13 of coronary thrombosis

Albert Schwartz, Cincinnati, Eclectic Medical College Cincinnati, 1916, member of the Ohio State Medical Association aged 57, died, December 19, of carcinoma of the neck

Alexander A Sharp, Chicago University of Pennsylvania Department of Medicine Philadelphia, 1886 also a lawyer, aged 80, died December 6, in the Henrotin Hospital of coronary heart disease and general arteriosclerosis

Charles Shattinger, Los Altos, Calif., St Louis Medical College, 1886, member of the California Medical Association served on the staff of the Palo Alto (Calif.) Hospital, aged 77, died, December 13, of acute cardiac failure, chronic myocarditis and arteriosclerosis

Hobart Parker Shattuck Cincinnati, Los Angeles, Cornell University Medical College, New York 1903, aged 64, died, December 10, in the California Hospital of carcinoma of the stomach

Carl A Sherrill, Medina, Texas, University of Tennessee Medical Department, Nashville, 1898 aged 70, died, December 15, in Galveston of coronary occlusion

Richard Anderson Smith, Omaha, John A Creighton Medical College, Omaha, 1915, for many years physician and surgeon for the Union Pacific Coal Company at Hanna, Wyo., aged 53, on the staff of the Immanuel Hospital, where he died, December 18, of cerebral subdural hemorrhage arteriosclerosis and diabetes mellitus

August Stark, Albany, Ore., University of Oregon Medical School, Portland, 1901, aged 78, died December 4, in the Albany General Hospital of injuries received when struck by an automobile on November 13

Henry Syle Stern Cincinnati, Richmond, Va., Medical College of Virginia, Richmond, 1914, associate professor of pediatrics at his alma mater, specialist certified by the American Board of

Pediatrics, Inc., member of the American Academy of Pediatrics served with Evacuation Hospital number 18 during World War I aged 49, died, December 24, of heart disease

Frank Louis Stillman Cincinnati, Ohio, Bellevue Hospital Medical College, New York, 1881, specialist certified by the American Board of Otolaryngology at one time on the faculty as a lecturer in the sciences at Ohio Wesleyan University one of the founders of the Ohio Society for the Prevention of Tuberculosis member of the American Laryngological, Rhinological and Otolological Society, formerly on the staffs of the Grant and St Francis hospitals, aged 83, died, December 23, of senility

Thomas Thomassen Stixrud, Luebo Belgian Congo, Africa, North Carolina Medical College, Charlotte, 1913, for many years a medical missionary with the American Southern Presbyterian Mission and was connected with the McKown Memorial Hospital, aged 54, died, December 29, in Manchester, Mo., of coronary thrombosis

Francis Stolle Cincinnati, Dixon, Calif., Stanford University School of Medicine, San Francisco, 1913, aged 55, died, December 18, of coronary heart disease

Cornelius Francis Sullivan, Waterbury, Conn., Georgetown University School of Medicine, Washington D C, 1912,

served during World War I, aged 55, died, January 14, in the Veterans Administration Facility, Northport, of acute pericarditis

Fred Charles Thum, Louisville, Ky., Hospital College of Medicine, Louisville, 1898, Kentucky University Medical Department, Louisville, 1899, aged 68, died, December 24, in the U S Marine Hospital of mesenteric thrombosis and cerebral hemorrhage

Elmer E Thurber, Brainerdsville N Y., University of Vermont College of Medicine Burlington 1886 member of the Medical Society of the State of New York, aged 81, died, December 27, in Chateaugay of arteriosclerosis

William C Vigor, New California, Ohio Columbus Medical College, 1884 for many years served as clerk

of the Jerome Township school board, aged 82, died December 21, of cardiac valvular renal disease and myocarditis

David W Ward, Sparks Nev., Palmetum Medical College and Hospital Chicago 1888 aged 85 died, December 26 of injuries received when he was struck by an automobile

James Albertus Watkins, Uniontown, Ky., Kentucky University Medical Department, Louisville, 1903, aged 68 died, January 1, of influenza and organic heart disease

Richard Ferdinand Weirich Cincinnati, Marcellus Mich., Northwestern University Medical School Chicago, 1928, served for seventeen months in the photographic section of the air corps during World War I member of the school board of Marcellus, served as psychiatrist at the Michigan State Hospital, Kalamazoo, member of the attending staff of Three Rivers (Mich.) Hospital aged 47, died, December 25, in St Luke's Hospital, Chicago, of carcinoma of the lung

Frank A Williams, Lake Providence La., Mississippi Medical College, Meridian, 1909, served during World War I, health officer of Lake Providence, aged 55, died, December 1, in Tallulah of hypertensive heart disease

Robert Hamilton Williams Cincinnati Passed Assistant Surgeon, Lieutenant, U S Navy, Lynchburg Va. University of Virginia Department of Medicine, Charlottesville, 1938, was commissioned an assistant surgeon with rank of lieutenant, junior grade, U S Navy and later was appointed a passed assistant surgeon with rank of lieutenant aged 32, was killed in action in the battle of the Solomon Islands, November 13

KILLED IN ACTION

LIEUT. JOSEPH FRANCIS RUIZ, U.S. N. R., 1915-1942

LIEUT. ROBERT HAMILTON WILLIAMS, U.S. N. R., 1910-1942

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act and in cases in which they refer to drugs and devices they are designated D D N J and foods, F N J. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Dickson's Herb Lax Tonic—Addison H. Dickson trading as A. H. Dickson, Memphis, Tenn. Shipped May 3, 1940. Composition essentially epsom salt (approximately 28 grams per hundred cubic centimeters), small amounts of methenamine, salicylic acid, sodium benzoate, plant extracts including nuxvomica and a resinous substance such as podophyllum with a trace of iron and water flavored with peppermint oil. Misbranded because the product's name was false and misleading in representing that the mixture was a laxative compound composed entirely of herbs and derived its laxative properties solely from herbs whereas this effect was due in part to epsom salt, a mineral substance further misbranded because label falsely represented that the product would be helpful for indigestion, biliousness, nervousness, bad blood, rheumatism, urinary troubles and general rundown conditions.—[D D N J F D C 486, September 1942.]

Locao Belem—Belem Products Company, Houston, Texas. Shipped Nov. 1, 1940. Composition chiefly water, alcohol, a foam producer, perfume materials and a small amount of glycerin. Misbranded because label falsely represented that it was efficacious in treating baldness, falling hair, dandruff and irritated scalp; that ordinary dandruff or itching scalp would respond quickly to this treatment and that satisfactory improvement or even complete elimination of these conditions would result in from two to four weeks; that benefit would be shown in less severe cases of falling hair in a few weeks and in the more severe cases in from three to six months; and that the product would develop new growth on bald areas. Further misbranded because claim on cartons, Locao Belem, has been thoroughly analyzed by the Pure Food and Drugs Department of the United States Customs and Complies with rigid requirements of Pure Food and Drug Laws, was false and misleading since it had not been found by a government agency to be in strict compliance with the requirements relating to foods and drugs and it did not comply with the Federal Food, Drug and Cosmetic Act.—[D D N J F D C 487 and 507, September 1942.]

Neff's Gland Tonic—George G. Neff trading as Prostex Company, Miami, Okla. Shipped between March 22 and April 1, 1940. Composition essentially epsom salt, small amounts of ammonium alum, a mineral acid such as sulfuric acid, minute proportions of quinine compounds of potassium and iron and a nitrate in water. Misbranded because names "Gland Tonic" and "Prostex" in the labeling and accompanying circular were false and misleading in representing that this was a gland tonic and would be efficacious in treating prostate gland cases and kindred disorders of kidneys, bladder and urinary tract, colitis, dropsy, rheumatism and infected internal organs; that it would be of benefit in acute cases of prostatitis and dropsy and in eliminating infection and some other disorders.—[D D N J F D C 488, September 1942.]

No Wheez for Asthma—No-Wheez Corporation, St. Charles, Mo. Shipped between March 1 and May 24, 1940. Composition essentially small amounts of inorganic salts commonly found in mineral water with pine tar and an emodin-bearing drug and water. Misbranded because label falsely represented the product's alleged efficacy in treating asthma and hay fever in bringing lasting relief to asthma and hay fever sufferers and preventing wheezing in these conditions.—[D D N J F D C 489, September 1942.]

Pedimoll—Pedimoll Corporation, Los Angeles. Shipped April 25, 1940. Composition essentially a magnesium compound with small amounts of sulfur and cresol in an oil base. Misbranded because of false and misleading label representations that it would be efficacious in treating bunions, calluses, corns, sore swollen or sweaty feet, muscular soreness, most skin irritations, eczema and acne, athlete's foot, impetigo and sunburn; that its daily use would prevent suffering with one's feet and make walking a pleasure; that it would have a swift germicidal effect and safe healing action; that when used on any part of the body it would relieve conditions caused by muscular soreness and strain, swelling, itching, sunburn, bruises, infected bites, sore joints, varicose veins and some other things; that by its use children would be spared suffering from corns, calluses and infections; that it would reach deeply into the pores and purge the skin of impurities; that it would be effective in the treatment of nervous, wobbly, stiff, swollen, flabby, knotty legs; would tone the circulation, soothe the nerves, loosen knotted adhesions within the muscles and foster elasticity within hardening vein walls.—[D D N J F D C 490, September 1942.]

Correspondence

COOLING IN SHOCK

To the Editor—Apropos of your recent editorial entitled "Cooling in Shock" (THE JOURNAL, February 6, p. 432) it may be of interest to quote from two authors of olden times. Edmund Goodwyn, M.D., writing in 1788 on The Connexion of Life with Respiration, said:

it appears on the other hand from the result of many attempts to recover the hibernating animals from their torpor that when the circulation of the blood has ceased and the temperature of the body is reduced near the freezing point if heat be applied either very suddenly or in a very high degree the principle of life is soon destroyed whereas if it be applied gradually and in a very low degree to the same animals in the same circumstances the principle of life is often excited to action and the functions are soon restored.

To favour the recovery then most effectually [from the state of suspended animation] the application of heat should be conducted on the same plan, which Nature has pointed out for the torpid animals. It should be applied very gradually and uniformly and it may be raised to 98° but not further than 100°.

John Snow, writing in 1841 on Asphyxia, and on the Resuscitation of Still-Born Children (London M. Gaz. 29, 222, 1841-1842) says:

Dr. Edwards of Paris by a most extensive and beautiful set of experiments has found that newborn mammiferous animals die most slowly in water at about 60 degrees which is ordinary cold water and that they die much more quickly as the water approaches blood heat. Dr. Edwards advises that persons in the state of suspended animation should amongst other measures be exposed to the cool air and that the application of heat should be avoided unless indeed just a momentary application to endeavour to arouse sensibility. The Royal Humane Society however directs the application of warmth in all practicable ways not only as an auxiliary to artificial respiration but even to commence with if the means for the latter are not in readiness and most authors I believe coincide with the views of the Humane Society. Dr. Edwards considers it is by its effects on the nervous system and through that on the heart that a high temperature produces its effects. I think that although the nervous system may be affected and is probably the channel of its impression yet that the deleterious effects of an elevated temperature when respiration is stopped depend on its stimulating the capillary circulation of the system and thus promoting the de-oxygenation of the blood that change which is antagonistic of respiration which rules its extent under all circumstances and which in fact constitutes the necessity for having a respiration. But whatever view we take of this point the fact of the influence of temperature on asphyxia proves that the application of heat ought to be avoided until respiration is thoroughly established when it will no doubt be a useful auxiliary to restore sensibility and renovate the patient.

It appears that the beneficent effect of cold in reducing the demand by the tissues for oxygen was appreciated by some thoughtful physicians over a century ago. It is possible that certain case reports in the past of recovery after long periods of extreme respiratory and circulatory depression were unjustly discredited.

RALPH M. WATERS, M.D., Madison, Wis.

Department of Anesthesia, University of Wisconsin

PARALDEHYDE

To the Editor—In THE JOURNAL, January 16, the page caption for Dr. Burstein's paper on Paraldehyde Administration, "Hazard of Anesthesia," is misleading. A more fitting caption would have been "Hazard of Overdosage" or "Hazard of Intravenous Dosage." Paraldehyde has been extensively used in mental hospitals as a sedative. By reputation it is the safest of hypnotics, although pulmonary complications have followed continued administration of large doses. As a preoperative hypnotic, paraldehyde is an agent of distinct value. It is suited for rectal administration in a mixture with liquid petrolatum without need for special precautions in preparing the mixture. As it is excreted almost entirely by the lungs, it has no ill effect on liver or kidneys, a point of especial importance if these organs are already diseased. In 1935, intravenous administration of pure paraldehyde as an anesthetic was suggested by Beaumachin, Springer and Elliott, but only for the briefest of operations. Their method was a proper one for the difficult subjects to be found in mental hospitals. They made trial of

doses of from 5 to 19 cc but recommended 9 cc as the maximum intravenous dose

In case 1 of Dr Burstein's paper, death occurred following intravenous administration of 35 cc of paraldehyde. This result is not surprising, as the dose administered far exceeded the limit of safety. 35 cc is about four times the maximum intravenous dose recommended. The margin of safety for paraldehyde administered by rectum is much greater because of the slow rate of absorption from the liquid petrolatum mixture. The preoperative rectal dosage is from 15 to 30 cc administered with 60 cc of liquid petrolatum an hour before the operation. This dose produces a featureless sleep for about five hours. The safety of this procedure is attested by its large margin of safety. Two patients have by mistake received 240 cc of paraldehyde, eight times the maximum recommended dose, but have recovered without complications. Objections to the method are the penetrating odor of paraldehyde and the fact that in warm weather it attracts swarms of flies. In case 2 of Dr Burstein's paper the fatality is attributed to rectal administration of 35 cc of paraldehyde. While this is somewhat beyond the recommended dosage, in view of the great margin of safety of rectal paraldehyde demonstrated in other instances it is possible that the fatality was due to some factor other than the paraldehyde.

I commend Dr Burstein for his painstaking report on paraldehyde but take this opportunity to approve somewhat an agent which if not the safest of hypnotics, is certainly as safe as any.

ALBERT H MILLER, MD, Providence, R I

MUSCLE PHYSIOLOGY

To the Editor.—I have just read the editorial "Advances in Muscle Physiology" in the January 30 issue of THE JOURNAL. The last sentence states that the muscle of the body comprises approximately 25 per cent of the total body weight. I feel quite sure that this figure is wrong. Scammon states in the first chapter of Morris's Human Anatomy that "the voluntary musculature forms about one quarter of the body in the later part of fetal life and at birth and increases about twofold in relative weight by maturity."

Harry A Wilmer (Changes in Structural Components of the Human Body from Six Lunar Months to Maturity, *Proc Soc Exper Biol & Med* 43:545 [March] 1940) states that the postnatal changes in the relative distribution of components consist of a marked increase in the voluntary muscle from about one fourth to over two fifths of the body mass. A graph in this article shows that muscle makes up 43 per cent of the body in the adult.

Associate Dean, University of Utah School of Medicine

OCHRONOSIS

To the Editor.—In the Dec 19, 1942 issue of THE JOURNAL, page 1283, in an article by James W Smith on ochronosis, the statement is made that "Harvey Cushing's finding that the first British case of ochronosis had been diagnosed Addison's disease does not appear in the medical literature and is worth recording." On page 12, volume 2 and on page 698 in the single tome edition the reference to this case is made. The case was reported by Dr Frank M Pope (*Lancet* 1:24 [Jan 6] 1906). In the front of the Jan 6 1906 issue of the *Lancet* are about a half dozen colored illustrations of the case. In the article itself the 11 previously reported cases are mentioned and exact references are listed. I enjoyed Dr Smith's article but believe this is worth checking.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts Prescribing of Drugs and Use of Surgical Instruments by Chiropractor—Jones, a licensed chiropractor, was charged in an information filed by the prosecuting attorney of a county in Missouri of unlawfully practicing medicine and surgery in that he did attempt to treat a stated woman at a stated time and place by prescribing, dispensing and administering medicines and by using surgical instruments in performing an operation on her person. He was convicted and appealed to the Springfield (Mo) court of appeals.

The chiropractor contended that the information on which his conviction was based was defective in that because it failed to inform him what surgical instruments were used in performing the operation alleged and what medicine or medicines were prescribed it did not enable him properly to prepare his defense. The section of the Missouri medical practice act, answered the appellate court, under which the defendant was convicted reads, so far as is here material, as follows:

Any person practicing medicine or surgery in this state and any person attempting to treat the sick or others afflicted with bodily or mental infirmities without a license from the state board of health shall be deemed guilty of a misdemeanor.

The information filed in this case in charging the crime follows substantially the phraseology of the medical practice act. This is sufficient to constitute a valid charge where, as here, the statute describes the entire offense by setting out the facts constituting it. This having been done, it was unnecessary to enable the defendant properly to prepare his defense to name or describe the kind of surgical instrument or instruments used or the kind of medicine or medicines prescribed in informing the defendant of the nature of the charge against him.

The section of the medical practice act just quoted concludes with a provision that on receiving information that any of its provisions have been or are being violated the secretary of the state board of health, the agency charged with the duty of issuing and suspending or revoking licenses to practice medicine and surgery, shall investigate the matter and on probable cause appearing shall file a complaint with the prosecuting or circuit attorney in the county or city in which the alleged offense occurred. This provision, the defendant argued, sets forth the sole method by which prosecutions may be instituted, and consequently the prosecuting attorney in this case had no legal authority to file the information against him which was filed. Therefore, so his argument went, the trial court should have granted a motion he made to quash the information. The defendant's contention is untenable, said the court. True, the provision of the medical practice act just referred to does set forth a method for instituting a prosecution. This particular provision was inserted by the legislature obviously to require the state board of health to cooperate with prosecuting attorneys by giving information and filing complaints on these particular infractions of the law. This provision, however, by placing a mandatory duty on the state board of health and its secretary

was designed to help prosecuting officials, not to place a limitation, restriction or check on the general powers conferred on them by law.

The chiropractor next complained of an instruction which told the jury that the practice of chiropractic is defined by the laws of the state as being the art of palpating and adjusting by hand the movable articulations of the human spinal column for correction of the cause of abnormalities and deformities of the body and that a license to practice chiropractic does not authorize the holder thereof to treat the sick by the use of operative surgery or by the administration or prescription of any drug or medicine. It was entirely proper, in view of the evidence said the court, for the trial court to define the practice of chiropractic and to advise the jury that a license to do so would not justify the practice of medicine and surgery. There is nothing in the instruction that could have tended to prejudice the jury against the defendant.

The appellate court held further that the trial court properly refused to instruct the jury, as the defendant desired it to do, that if the jury found that the medicines furnished by the chiropractor to the complaining witness were such medicines as are generally used by the public without the prescription "dispensation" and administration by persons licensed under the laws of the state to practice medicine and surgery, the jury should find the chiropractor not guilty. The court likewise held it proper for the trial court to permit a licensed physician and surgeon to testify that he had examined the complaining witness after she had visited the chiropractor and that he observed clots of blood and strips of tissue which indicated that the complaining witness had undergone a miscarriage or an abortion. The defendant contended that the effect of this testimony was to leave the case in such a prejudicial condition that the inference would be given the jury that the miscarriage or abortion, evidence of which was observed by this witness, had been committed by the defendant. While, said the court, it is the general rule that evidence of other crimes independent of that for which the defendant is on trial is inadmissible, where evidence of another crime tends directly to prove guilt of the crime charged such evidence is admissible. Conversely, evidence which is relevant is not rendered inadmissible because it tends to prove the defendant guilty of some other crime. As is stated in Wharton's Criminal Evidence, 11th edition, page 487, section 345:

If the other crime and the crime charged are so linked together in point of time or circumstances that one cannot be fully shown without proving the other regardless of whether the crime incidentally shown is of the same or a different character from the one on trial the general rule of exclusion does not apply. If evidence is competent material and relevant to the issue on trial it is not rendered inadmissible merely because it may show that the defendant is guilty of another crime.

The judgment of conviction was accordingly affirmed.—*State v Jones, 164 S W (2d) 85 (Mo, 1942)*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Ovarian Insufficiency and Decreased Stature.—Albright, Smith and Fraser describe a syndrome of short stature and sexual infantilism which is due to primary ovarian lack rather than to primary pituitary disease. The features which characterize this syndrome are short stature, infantile breasts, uterus and vagina, a small amount of axillary and pubic hair, good physical well being, retarded osseous development, an increase above normal of the follicle stimulating hormone and decrease of 17-ketosteroid in the urine, the development of normal amounts of axillary and pubic hair on estrogen therapy, a normal hypoglycemia responsiveness to the insulin tolerance test, frequent congenital anomalies in addition to the absence or malformation of the ovaries, diffuse osteoporosis and precocious senility. Eleven cases of the syndrome are presented. It is to be differentiated from panhypopituitarism, "premenarchal menopause precoc" and a selective deficiency of the gonadotropic substance of the anterior pituitary. Evidence is presented which suggests that in females the hormone of the adrenal cortex causes axillary and pubic hair growth. Five hypotheses are discussed as causes for the syndrome. The authors believe it results from decreased functioning of the adrenal cortex caused by decreased-pituitary stimulation of the adrenal cortex, which in turn results from decreased estrogen production. Turner's syndrome—congenital webbing of the neck, sexual and somatic infantilism and cubitus valgus—is a subform of this syndrome. Replacement therapy with estrogen,

in addition to increasing the general well being and stimulating the growth of the breasts and axillary and pubic hair, probably leads to an increase in the rate of epiphyseal growth in those subjects whose epiphyses are still united.

"Epinephrine Shock."—Engel and his associates describe an unusually severe instance of hyperepinephrinemia in a woman of 23, in whom attacks were induced by the most simple physiologic stimuli for epinephrine discharge such as fear, anger, before meals during sexual intercourse and during the induction of anesthesia when apnoea was probably the factor. The attacks, which began two and a half years ago, lasted as long as thirty-six hours, often terminating with a clinical picture suggesting so called epinephrine shock. A pheochromocytoma was suspected. During the first exploration on the left side, anesthesia precipitated a severe attack and a phlebotomy was performed because pulmonary edema developed. Exploration failed to reveal a tumor, and the patient continued to have frequent mild attacks. Roentgen study by perirenal insufflation of 550 cc. of oxygen into the right perirenal space suggested a small mass in the right adrenal area. Preoperative preparations were made to "sterilize" the adrenal as is done with the thyroid in exophthalmic goiter. The renal area was exposed through a right lumbar incision and a tumor the size of a large plum was removed. As soon as the tumor was palpated, the blood pressure rose from 120 to 220 mm. systolic and remained at this level until the last vessel to the adrenal gland was ligated, when it dropped precipitously to 110 mm. and then to 70 mm. Microscopically the tumor had the characteristic structure of a pheochromocytoma. Biopsy of each gram of the tumor caused a reaction in the denervated cat's iris, a retraction of the micturating membrane and a blanching of the sympathetomized ear equivalent to that caused by 8 mg. of epinephrine. It also caused the cat's blood pressure to rise. The patient has been free from spontaneous attacks for three months. There was no evidence of insufficiency of the adrenal cortex either by electrolytic studies or from the subsequent course.

Single Combined Treatment for Gonorrhea.—To speed the recovery from uncomplicated gonorrhea Ferguson and his associates developed a high concentration of sulfathiazole in the patient and subjected him to hyperpyrexia. Their patients were seamen aged from 19 to 47 years who were infected with various gonococcus strains from many countries. The number of previous infections varied from zero to five and the duration of infection from one to sixty days. The patient after a physical examination and the taking of cultures and smears to confirm the diagnosis, was given 1 Gm. of sulfathiazole starting at 2 p. m. and continued every four hours until a total of 5 Gm. was administered. After this he was given an enema and then a hot tub bath which brought the surface temperature to about 102 F. The patient was then put into a preheated fever cabinet and his rectal temperature was slowly raised to 106 F. This took about one hour. This temperature was maintained for about seven hours. During his stay in the hypotherm cabinet the patient was given 3 to 4 liters of isotonic solution of sodium chloride flavored with syrup. Following treatment he is warmly wrapped in blankets, brought to his room and given fruit juices and milk for the next twenty-four hours. The criteria of cure included cessation of all objective symptoms, disappearance of discharge and dysuria and a clear urine in the two glass test. For the bacteriologic and cultural examinations, on the second and then on the fourth or fifth day (for three times) after the fever therapy, a sound was inserted, the urethra was massaged gently against the sound, the sound was removed and the prostate was massaged and the strippings were examined microscopically and culturally. Three consecutive negative cultures were required for discharge. Of 25 patients with uncomplicated previously untreated gonorrheal urethritis given sulfathiazole and fever therapy 88 per cent were cured, of 20 receiving this therapy after one course of a sulfonamide compound 90 per cent were cured, of 26 receiving the combined therapy after more than one course of a sulfonamide compound 85 per cent were cured, 2 men with epididymitis recovered after one course of combined therapy and only 2 of 4 given two combined treatments recovered.

Blood Pressure and Thiocyanate—The use of thiocyanate in the treatment of hypertension is substitution therapy. It supplies thiocyanate to hypertensive patients, who as a group have less thiocyanate in the blood than other individuals. The treatment apparently is required for life. Best results are obtained in less severe cases. Treatment should be started before there is too much sclerosis of the arterioles. Relief of symptoms can be expected in practically all cases. Functional results are good in two thirds, while one third of the patients show poor or fair results. Proper selection of patients would greatly increase the percentage of good results, but such selection is not justified because of the benefit that patients obtain from fair results and from symptomatic improvement. The underlying factor in failure is fibrosis of the arterioles and capillaries. Fair results after prolonged therapy may be had in old arteriolar sclerosis itself as well as in syphilis, hemiplegia and cardiac decompensation. Of the 136 patients of Caviness and his co-workers 92 have shown good results, i. e. a sustained reduction of at least 15 per cent in both the systolic and the diastolic pressure. Better results are obtained in private than in clinic and institutional patients. A reduction of 15 per cent is sufficient to relieve symptoms and decrease the danger of hemiplegia and angina. None of the patients have died. Best results were obtained when there was a low natural blood thiocyanate concentration, when a satisfactory response followed small doses of thiocyanate and with a blood concentration of 2.5 to 5 mg. of thiocyanate per hundred cubic centimeters of blood while on treatment.

Progesterone for Uterine Bleeding in Girls—Menstrual records of 24 adolescent girls and young women with functional uterine bleeding to whom Allen and Heckel gave progesterone or anhydrohydroxy progesterone are listed. The effect of the drugs on the menstrual pattern was observed for many months. In general, the administration of approximately 30 mg. of progesterone (5 mg. daily) caused a cessation of bleeding within ten days of the last injection. Progesterone deprivation bleeding occurred frequently, explaining the bleeding during the first few days after therapy. In about one third of the subjects, normal cycles occurred for four months or more after therapy, whereas in another third there was a recurrence in less than four months but not in the first month. In the final third, amenorrhea followed immediately or after two or three cycles.

Gynecologic Lesions and Hypertension—Observations which suggest that hypertension may result from partial ureteral occlusion are presented by Everett and Scott. Among the 100 women with uterine fibroids, ovarian cysts, pelvic inflammatory disease and other pelvic disorders that they studied, 36 were found to have some degree of arterial hypertension. The patients' average age was 37.06 years, only 14 of the 36 were more than 50. Further analysis revealed that 25 of those with hypertension were in the group of 50 showing pelvic and ureteral dilatation. In a study of results of appropriate treatment on

the urinary tracts in 30 of these 50 patients the authors tried to find some common factor, such as infection of the urinary tract or pelvic inflammation, which might explain the failure of the urinary tracts to return to normal following treatment. Neither of these factors seemed to answer the question, and although it is difficult to show statistically it is the authors' impression that an extremely important factor was the length of time over which the gynecologic lesions in question have persisted. Therefore it seems that in the case of pelvic inflammatory disease and especially in the lesser degrees of uterine prolapse, surgical intervention should not be delayed too long. If, after a conservative regimen of palliation and chemotherapy, patients with pelvic inflammation continue to harbor masses causing the signs and symptoms of acute inflammation, the masses should be removed. A young woman with a relaxed pelvic floor and a moderate uterine prolapse should have a conservative repair operation compatible with future childbearing in preference to delaying it until her family is complete and then having a more radical procedure performed.

The Sulfonamides for Gonorrhea—From their data on the diagnostic value of cultural and smear methods Douglas and his associates conclude that the cultural methods are superior. They compared the therapeutic value of sulfanilamide, sulfathiazole and sulfadiazine as to dosage, duration of treatment and effect of social and economic factors, pregnancy, race and age in the one hundred and eighty-five admissions of 158 patients with gonorrhea admitted to the New York Lung Hospital, 25 were admitted twice and 2 three times (for new infections). Sulfanilamide was used 64 times, sulfathiazole 62 and sulfadiazine 59. The latent form of the disease is often asymptomatic or associated only with leukorrhea (43 per cent) and frequently cannot be recognized without the aid of cultures. The efficacy of treatment is unaffected by age, color, pregnancy, duration of the disease or the site of the infection. Treatment and its control are more efficient if the patient is hospitalized. Of the three drugs employed, sulfanilamide was the least specific and the most toxic. Sulfadiazine appeared to be slightly more efficient and less toxic than sulfathiazole. Bacteriologic cure was most frequently encountered within nine to twelve hours after sulfathiazole or sulfadiazine and forty to fifty hours after sulfanilamide was administered. The most satisfactory therapy at present is 4 Gm. of sulfadiazine or sulfathiazole in divided daily doses for six consecutive days. Bacteriologic cure was established in one hundred and eighty of the one hundred and eighty-five admissions.

Acute Illness Among Cotton Workers—According to Schneider and his collaborators, since April 1941 reports of outbreaks of an acute illness among cotton workers have been received from twenty-five states and two Canadian provinces. More than 700 cases were reported from one state alone. The illness occurred among workers exposed to high dust concentrations, and its severity varied with the degree of exposure. The illness was characterized by sudden onset, one to six hours after exposure, and the short duration of its acute phase, usually twenty-four to forty-eight hours after exposure. The principal subjective symptoms were conjunctival irritation sub-

sternal oppression, dryness of the throat, generalized itching, fatigue, headache, cough, chills, fever, anorexia, nausea and vomiting. During the investigation one hundred and fifteen samples of cotton, cotton dust, linters, cotton plant debris, cotton seed and soil were received from fourteen states, the U. S. Department of Agriculture and two Canadian provinces. All the samples of cotton incriminated in outbreaks were dusty, low grade and stained, and they contained varying amounts of plant debris. The samples contained no toxic gases, chemically extractable substances, insecticides or pathogenic fungi but they did contain a gram negative rod shaped bacterium in numbers ranging from 3,000,000 to more than 10,000,000 per gram. It was not isolated from high grade cotton. Seventy of eighty-one samples of materials reported to have caused illness contained the same strain of this bacterium. The bacterium has been tentatively placed in the genus *Aerobacter*. A heat stable endotoxin-like substance was demonstrated in filtrates from saline extracts of stained cotton, in filtrates from broth cultures and in killed suspensions. It is believed that this toxic substance is in the nature of an endotoxin because of its heat stability, lower antigenic capacity and increase with age of culture or destruction of cells. The severity of symptoms and physical changes was dependent on the concentration of the cotton bacterium or its products in the cotton dust inhaled and on the duration of exposure. Intradermal injections of the filtrate to man resulted in severe inflammatory lesions characteristic of acute intoxication rather than of hypersensitivity. As this acute intoxication resembles mill fever, Monday fever and gun fever in cotton mill workers and respectively, healing fever, mill fever, grain fever and hemp fever in workers inhaling flax, jute, grain and hemp dust, the toxic products liberated by the cotton bacterium or some closely related species may be the etiologic agent for these diseases.

Hormones and Carcinoma of Prostate.—His own experience with estrogen in about 60 patients with prostatic carcinoma is still too meager for Creevy to draw definite conclusions, but he is convinced that the work of Huggins and his followers constitutes a major contribution to the comfort of old men and that its full possibilities are to be explored. Some investigators have reported the disappearance of all the characteristics of prostatic cancer on rectal examination and on metastasis to bone on roentgen examination but he has seen both regress but not disappear. Estrogens should be tried in every case of prostatic cancer not in the gland itself, and if they fail only then should castration be performed.

Malaria Mortality in the Southern United States.—Faust and De Bakey believe that the low malaria mortality rate for 1940 helps in discovering the chronic foci of the disease. Analysis of the malaria mortality data for the United States, especially for the Southern states, reveals a continued reduction especially since 1938 to an apparently all time

average low of 302 for the fourteen endemic malaria states in the South. With a population of one third of the entire nation the South had 96 per cent of the reported malaria deaths in 1940. These deaths occurred in 34 per cent of the counties in the fourteen states. There has been a favorable reduction in the number of counties in the South contributing to deaths. There was an apparent suppression of the five to seven year cyclic increase, which should have occurred in 1938-1940 in the South, in malaria deaths. The factors responsible for the decrease in rate since 1938 are unknown but may be due to better economic conditions of the poor, that is, better food, more funds for the purchase of antimalarial drugs and the screening of homes. Also intensive measures have been carried out to suppress or to reduce the number of Anopheles mosquitoes. Evidence indicates that *vivax* malaria has similarly decreased. The present reduced trend should not tend toward complacency, as reduced control may allow recrudescences to occur in endemic foci. As long as susceptible malaria mosquitoes breed, new infections may be introduced from tropical America and thus "seed" the country with new, possibly more virulent strains of malaria plasmodia. Possibly with continued treatment of malaria patients in endemic foci the gametocyte rate may become so low that mosquito infection will be difficult leading temporarily to a condition of anophelism without malaria. Outside the Southern states there were only fifty-seven malaria deaths in the United States in 1940. Several of these were of drug addicts, while many of the others were probably the result of exposure to infection in the South or in tropical America.

Nutritional Status Evaluation in Madrid—A study of the nutritional status of 561 persons of a low economic level was carried out by Robinson and his colleagues in an industrial suburb of Madrid during the summer of 1941. The combined dietary records of the family food consumption indicated an average intake of calories and calcium far below maintenance levels, and a protein intake of questionable adequacy. The levels of iron, phosphorus, thiamine and ascorbic acid appeared generally adequate for maintenance, those for vitamin A and riboflavin were at or below the borderline. Clinical examination revealed almost universal evidence of quantitative (caloric) underfeeding. Classic deficiency disease was rare; there were 2 instances of nutritional edema, 1 of chronic pellagra and 3 of rickets. Search for the early manifestation of these diseases disclosed a significant number of persons with cutaneous lesions attributable to vitamin A deficiency and a fairly high incidence especially among the females, of capillary invasion of the cornea which was probably due to arboflavinosis. In addition, many of the persons had signs and symptoms of a mild neural or neuromuscular disturbance of undetermined origin. About one third of the subjects had a mild macrocytic hyperchromic anemia, and the incidence of hypoproteinemia among males was 11 and among females 5 per cent.

Vitamin B Complex and Manual Labor—Johnson and his co-workers subjected 10 men to hard daily physical work on a diet deficient in parts of the B complex, notably thiamine. During the first week of the experiment 5 of the men were given daily 2 mg of thiamine hydrochloride, the other 5 were given placebos. During the third week (one week was spent in preliminary observations with the men on a normal diet) of the experiment all subjects received daily doses of 18 Gm of brewers' yeast containing 0.5 mg of thiamine. At the end of the second week all subjects complained of easy fatigue and their physical fitness had definitely deteriorated, this was

greater in the subjects not given thiamine hydrochloride, most of whom exhibited symptoms, sometimes acute, of muscular and articular pains, lack of well being, poor appetite and constipation. These symptoms were mild or absent in those receiving thiamine. All these symptoms disappeared during the week that brewers' yeast was taken. The usual level of fitness was regained more rapidly and more completely by the subjects who had received thiamine during the first week. Changes in the electrocardiograms of certain subjects in both groups, noticed at the end of the deficient period disappeared by the end of the yeast period. At the end of the week the daily urinary excretion of thiamine by those who had not received this vitamin was well within the range of deficiency. The conclusions are that when men are doing hard physical work, even for a few days it is imperative that they have an adequate daily intake of the whole vitamin B complex if physical fitness is to be maintained. Of the vitamin B complex, thiamine alone will not maintain physical fitness of laborers in single daily doses of 2 mg, but brewers' yeast appears to be a complete and adequate supplement for a diet grossly deficient in the vitamin B complex. When the addition of vitamin B complex to a ration (as in emergency rations of troops and sailors separated from bases) is indicated yeast would seem to be a certain source of all the necessary components.

Decompression of Chest in Dysphagia—Newton and Levine report a case in which pronounced dilatation of the heart, especially of the left auricle due to rheumatic valvular disease caused dysphagia. The chest was decompressed by removal of portions of the third, fourth and fifth ribs anteriorly. The dysphagia disappeared and there was a distinct improvement in the condition of the heart. Palpitation was less troublesome, the heart rate could be slowed more satisfactorily and the patient's general strength improved. The patient lived for almost nine years after the operation. At necropsy the heart was found to be substantially dilated; it weighed 590 Gm. There was decided mitral insufficiency with slight stenosis and slight stenosis of the aortic and tricuspid valves. The pericardial cavity was entirely obliterated by thin, old fibrous adhesions. The esophagus was displaced slightly to the right.

Cutaneous Disturbances in Diabetes Mellitus—Rudy and Hoffmann present 5 case reports which demonstrate that the cutaneous disturbances in diabetes mellitus are most frequently due to a vitamin deficiency, especially that of nicotinic acid. The authors have seen many more diabetic patients with similar more or less pronounced cutaneous eruptions. The skin of some of these diabetic patients is not unlike that of pellagrins. Its vulnerability to any kind of external irritation (rubbing or other mechanical or chemical trauma, perspiration, heat or sunlight) and to infections especially those due to monilia, is increased. Vulvitis as well as pruritus vulvae and am in diabetes are proved signs of pellagra and are due to a nicotinic acid deficiency. The most frequent manifestation is a vivid, more or less indurated erythema characterized by a violaceous or brownish color and a definite shiny surface. Fine lamellar peeling or psoriasiform scalliness, more or less deep ridging of the papillary lines and fissuring edema, blistering, maceration and even superficial ulceration vary the morphologic picture. Superinfection with monilia on predisposed regions suggests intertrigo or paronychia. Pruritus vulvae in diabetes does not respond to local treatment and does not always clear up with the control of glycosuria. In the authors' patients improvement followed the administration of nicotinic acid or its amide with, and at times without, the addition of vitamin B complex. This occurred even in the presence of glycosuria and hyperglycemia. Nicotinic acid, like thiamine chloride, is essential for the satisfactory oxidation of carbohydrate foods. This explains why some cutaneous manifestations appear for the first time or become aggravated after the diabetes is controlled. In such cases the symptoms disappear with the addition of the nicotinic acid. The same happens with other vitamins, such as riboflavin and thiamine hydrochloride. It is not unusual for a neuritis or perleche to become manifest or aggravated following the control of the diabetes or diabetic acidosis. The vitamin deficiency in diabetes mellitus may affect the gastrointestinal tract including the mouth, the central and peripheral nervous system and the genitourinary tract. The degree of the cutaneous infection depends on the severity of the vitamin deficiency and not on the glycosuria or hyperglycemia. The predisposing factors in the development of deficiency in diabetes mellitus are a diet deficient in the components of the vitamin B complex, disturbance of absorption and assimilation, and impaired hepatic function. The precipitating factors may be loss of weight, infection, gastrointestinal disturbance, operations, acidosis and intemperance.

Plasma Prothrombin and Hepatic Function—The hepatic function, as measured by the prothrombin, van den Bergh and bromsulphalein tests, was determined by Kapnick and his associates for 68 patients receiving sulfonamide therapy for acute infection. There was a significant decrease in the prothrombin

level of 14 patients during chemotherapy. The severity of the infection seemed to be more significant as the cause of prothrombin depression than did the type of sulfonamide used. A decreased prothrombin time may be the consequence of factors other than impaired hepatic function. Since serious infection and the sulfonamides are prejudicial to the welfare of the liver, it seems that some test of hepatic function should be used as a routine procedure with this group of patients. A decrease in plasma prothrombin is found early in impending hepatic failure. It is suggested that prothrombin determinations by the Quick method be done every three days on seriously ill patients receiving sulfonamide therapy. In this way patients in whom serious hepatitis is apt to develop would be recognized before the symptoms became clinically alarming.

Pleural Reflex Syncope and Air Embolism in Pneumothorax—Although concrete evidence proving the existence of pleural shock is not to be found in the literature Ormond believes that the condition exists. He reports 5 cases of this symptom complex. 2 were possibly due to pleural shock and in 3 there was definite air embolism. The symptoms of pleural shock are generally indistinguishable from those caused by air embolism. The symptoms usually appear suddenly at a moment when the needle is entering or leaving the pleural space. The psychic symptoms are giddiness and loss of consciousness, the motor, tonic and occasionally clonic spasms flaccid paralysis with contractions hemiplegia or monoplegia, and the circulatory and respiratory symptoms are rapid weak, irregular pulse pallor of the skin and cyanotic patches over the face neck and thorax. Pleural shock should be spoken of only when embolism can be excluded. One example of the existence of pleural shock is the patient with tuberculous empyema, whose chest has to be repeatedly aspirated and who goes into mild shock when the visceral pleura is irritated. Pleural shock has been observed in oleothorax, pleural exploration, pleural tap and simple pleural lavage. Many of these accidents in the pneumothorax procedures may be avoided by the proper choice of patients, proper examination, careful study of the roentgenograms, use of proper instruments and careful manometric readings.

Early Diagnosis of Shock—It is more important to detect the earliest signs of shock, says Royster, than to know the advantages and disadvantages of the various available means for combating it. A cold and clammy skin, rapid and thready pulse, low or absent blood pressure and ashen pallor are not signs of shock but of impending death. These signs indicate that the condition is approaching or has reached the point of becoming irreversible. The common denominator of all theories of the production of shock and all systems of treatment is a decrease in blood volume in relation to the total capacity of the circulatory bed. Whatever the remote factors involved the

peripheral circulatory deficiency which manifests itself as shock results from a disparity between the circulating blood volume and the volume capacity of the vascular system. Continued operation of the factors causing fluid loss depletes the stores of sodium in the interstitial spaces, and the delicate balance between the predominance of sodium outside the body cells and the predominant potassium within them is upset. In developing shock the two ions may effect a startling reversal. In simple, uncomplicated and not profuse hemorrhage the patient responds well to the introduction of whole blood, saline solution or plasma. The normal or artificial compensation results in hemodilution. Hemoconcentration is the earliest practicably measured change which occurs in shock. If unchecked, further hemoconcentration results and the vascular system becomes more constricted. The process is still reversible, provided the causative factor is not too overwhelming or too persistent in its action. The intravenous introduction of plasma or whole blood will usually save the patient, even though these elements are often lost through the damaged capillary walls. With excessive amounts of fluid loss and vascular damage a point is reached at which further vascular constriction is no longer possible. The reduced circulatory pressure results in tissue anoxia, and tissue anoxia causes a further demand on the capillaries for dilatation and permeability. To wait for a fall in blood pressure before diagnosing and treating shock is like waiting for general peritonitis to develop before making the diagnosis of appendicitis. Hemoconcentration appears sooner than any measurable fall in blood pressure. It takes no more time than it does to make a leukocyte count. Another method of arriving at the same conclusion is by determining the hematocrit. This reading roughly parallels the erythrocyte count in nonanemic persons. The use of the densimeter to determine the falling drop time takes only two or three minutes. The advantage of this apparatus is that in one operation the density of the blood is determined and a quantitative estimate of the type of fluid necessary is obtained. The hemoconcentration test can be used for following the effect of treatment.

Metrazol in Auricular Paroxysmal Tachycardia—Boyd tried unsuccessfully all the recognized procedures and drugs to abort a prolonged paroxysm of tachycardia. He gave $1\frac{1}{2}$ grains (0.1 Gm) of metrazol intravenously and noted almost immediate improvement in the patient's general condition. The attack ceased within two or three minutes. He has used the drug for 11 patients who did not respond to vagovagal stimulation, with almost immediate relief in all but 1. This patient responded to an intravenous dose of 12 grains (0.8 Gm) of digitalis. The response in these patients and those of other physicians may have been coincidental, but the author believes it is due to the action of the drug, since the response has been uniform in all.
